INDIA: The Golden Temple, chief shrine of the Sikh religion, at Amritsar.

INDIA, in'di-ā, a republic of southern Asia. It is one of the two nation states which came into existence on Aug. 15, 1947, when the British Indian Empire was simultaneously given independence and partitioned into India and Pakistan. The seat of government is at Delhi, which has a population (1961 census) of 2,344,051. Including the protected state of Sikkim, the area claimed by the Republic of India is 1,264,012 square miles (the status of some of this area is disputed by Pakistan), and its population totaled 439,233,904 at the 1961 census. The national anthem is the *Jana-gana-mana*, with words by Rabindranath Tagore. The national flag has three horizontal stripes of equal width, the top saffron, the middle white, and the bottom dark green. In the center of the white stripe is Asoka's wheel. The coat of arms, derived from a pillar erected by Asoka at Sarnath, also shows the wheel.

Coat of Arms of India

Until 1947 the entire region now constituting the republics of India and Pakistan was known by the single term "India." This was in accordance with long practice. The ancient Greeks called the region *India*, meaning "the land of the Indoi," that is, of the people living near the River Indos (Latin, Indus). The basic Greek form *Indos* was an adaptation of an Old Persian and Avestan word, *hindu*, applied to the province of the Achaemenid Empire adjacent to the Indus River and meaning "land of the [great] river." The Old Persian in its turn was cognate with the Sanskrit word *sindhu*, "river," especially "the river [the Indus]." The Greek adjective to indicate something pertaining to the region was *Indikos*, "Indic," equivalent to the commoner English adjective "Indian."

The partition of the region brought the use of these terms into question. Since "Pakistan" and "India" referred to two political units, the old term "India" acquired a double usage. It applied in a wide sense to the whole geographic area and in a narrow sense to the recently demarcated nation. Many persons, especially those living in Pakistan, objected to the wider usage. A similar problem arose in connection with the phrases "subcontinent of India" and "Indian subcontinent" as applied to the wider area, and a certain vogue came to be attached to the designation "Indo-Pakistan subcontinent." In place of this awkward compound there is also used the appellation "South Asia," which generally has an inclusive application to India, Pakistan and Ceylon (with Nepal, Bhutan, and frequently also Afghanistan). Most writers on nearly all aspects of the subcontinent's life who are concerned with the period up to 1947 tend to retain the old and established forms "India" and "Indian," while commentators on political affairs since that date sometimes use the newly coined "Indo-Pakistan."

The people, land, economy, culture, and history of India are discussed under the headings listed below. With the exception of those dealing with the dance, music, and drama, linguistic science, languages, literature, science, religion and philosophy, prehistory, and history, in which the subcontinent is treated as a whole down to the time of its partition, the headings refer to the Republic of India. (For developments in the other major part of the subcontinent, see PAKISTAN.)

1. POLITICAL DIVISIONS

The Republic of India's constituent political units are the distillate of a complex process of integration which followed the arrival of independence in 1947. At that time, the portion of the subcontinent included in the newly formed Union of India was composed of all or part of 9 former governor's provinces and 5 former commissioner's provinces of British India, plus more than 500 states ruled by native princes under treaty with the British. In the following decade the various provinces and states were gradually consolidated and refashioned to make them as nearly equal in status and linguistically homogeneous as pos-

sible. Under the States Reorganization Act of 1956 the territory of the republic was divided into 14 states, 7 territories, and a protected state. In 1960, Bombay was divided into the 2 new states of Gujarat and Maharashtra, and in 1961–1962 former Portuguese possessions were incorporated in India as 2 territories: Dadra and Nagar Haveli; and Goa, Daman, and Diu. A 16th state, Nagaland, is in process of formation.

AREA AND POPULATION OF THE STATES AND TERRITORIES OF INDIA

Component	Area (square miles) ¹	Population (1961)	Capital
<i>States</i>			
Andhra Pradesh	106,052	35,983,447	Hyderabad

Total	1,264,012	439,233,904	

¹ Revised in January 1961 pending final surveys of boundaries by the Survey of India. ² Includes North-East Frontier Agency and Nagaland. ³ Temporary. ⁴ Status in dispute with Pakistan; area for entire state, population for Indian-held area. ⁵ 1962. ⁶ 1960. ⁷ Includes Pondicherry, Karikal, Yanam, and Mahé, formally ceded by France in 1956 (cession completed in 1962).

The 15 principal states enjoy equal constitutional position in the federation, and each has its own bicameral or unicameral legislature. The official languages of each of the states are as follows: Andhra Pradesh, Telugu; Assam, Assamese; Bihar, Hindi; Gujarat, Gujarati; Jammu and Kashmir, Kashmiri; Kerala, Malayalam; Madhya Pradesh, Hindi; Madras, Tamil; Maharashtra, Marathi; Mysore, Kannada; Orissa, Oriya; Punjab, Panjabi; Rajasthan, Hindi; Uttar Pradesh, Hindi; and West Bengal, Bengali. Less completely integrated into the political structure are the territories: Himachal Pradesh, in the Punjab Himalayan area; Manipur, on the Assam-Burma border; Tripura, an enclave jutting out of Assam and almost entirely surrounded by East Pakistan; Delhi, which includes Delhi, the nation's capital, and its immediate hinterland; the Andaman and Nicobar Islands; the Laccadive, Minicoy, and Amindivi Islands; Pondicherry (Pondichéry), which includes Karikal, Yanam (Yanaon), and Mahé, former French possessions; and Dadra and Nagar Haveli (Nagar Aveli), and Goa, Daman (Damão), and Diu, former Portu-

guese possessions. Within Assam are the North-East Frontier Agency, administered by the president of the republic acting through the governor of the state; and the State of Nagaland, created in 1962. Sikkim is a protected state.

The basic political unit below the level of the state is the district, the primary building block of the Indian polity. It is at this level that all local administration is coordinated in the offices of the district collector and the district magistrate, which are frequently held by one person. There are wide variations, but most states have 15 to 20 districts, each of about 3,000 to 5,000 square miles and 1 million to 2 million inhabitants. A number of districts may be loosely grouped into a division headed by a commissioner, and below the district level there are usually from three to five subdivisions. Each subdivision is in turn divided into units called taluks or tehsils (tahsils), depending upon the part of the country, and finally into villages and towns or cities. The largest cities (with 1961 census populations for greater cities) are Calcutta (5,550,195), Bombay (4,152,056), Delhi (old and new cities, 2,359,408), Madras (1,729,141), Hyderabad (1,251,119), Bangalore (1,206,961), Ahmadabad (1,206,001), Kanpur (971,062), Poona (737,426), Nagpur (690,302), Lucknow (655,673), Howrah (512,598), Agra (508,680), and Varanasi (Banaras, 489,864).

RICHARD D. LAMBERT,

Professor of Sociology, University of Pennsylvania.

2. THE PEOPLE

Prehistoric Cultures.—The earliest human skeletal remains of the Indian subcontinent discovered in sites which can be confidently dated belong to the Harappa civilization, which flourished in the 3d and 2d millennia B.C. There is, however, archaeological evidence to show that man of a type or types unknown inhabited the subcontinent from the beginning of the Middle Pleistocene period. Various sites have yielded tools which afford a picture (though still obscure in many respects) of the Indian Stone Age. Two distinct manufacturing traditions are known for the Paleolithic period (Old Stone Age). One of them, with its main focus in the Potwar region of what is now West Pakistan, is called the Sohan (Soan) industry; its characteristic implements are pebble choppers, chopping tools, and flake implements. The second, known chiefly from sites in peninsular India, particularly in the vicinity of Madras but also in the Potwar region, is termed the Madras industry; this produced a different type of implement which was formed from the core of a pebble and not from flakes detached from the core. The archaeologist Hallam L. Movius, Jr., has expressed the view that the first has definite affinities with a culture known in northern China, upper Burma, and Java, while the other belongs to a great complex occurring in the Middle East, Europe, and Africa.

Succeeding phases of the Stone Age in the subcontinent are not fully known. Microlithic industries, perhaps introduced by a new ethnic element from the West, are widespread and have a long history, but they cannot be satisfactorily dated. Moreover, while polished stone implements such as characterize a Neolithic stage elsewhere have been found in large numbers, the existence of a true Neolithic stage—one in which agriculture and pottery making but not metallurgy were practiced—has not been definitely established.

[illegible]

Racial Composition of the Modern Population.—The people of India are not physically homogeneous. Biraja Sankar Guha, in *Racial Elements in the Population* (London 1945), distinguishes six major racial strains which have amalgamated in varying degrees to form the modern population. One of these, termed the Mediterranean because of its prominence in that area, is characterized generally by a long head, moderate stature, a slight build, and dark skin. What appears to be an ancient type of this Mediterranean strain, in which the head is long and narrow with a high cranial vault, the face narrow, the nose small and moderately broad, the skin dark, and the hair wavy or curly, is the dominant physical type among the Dravidian-speaking peoples of south India. The evidence is as yet insufficient to determine when this type first entered India, but it is thought to have preceded the second and somewhat different Mediterranean type which formed an important element in the population of the Indus Valley during the period of the Harappa civilization, and which is prominent in north India today as well as among the upper castes throughout the country. As compared with the first type, this second type is taller and often lighter skinned; the nose is prominent, narrower, and less fleshy; the cranial vault is lower; and the growth of hair on face and body is more luxuriant. In the Punjab, Rajasthan, and western Uttar Pradesh in north India, and occasionally in the rest of the country, a third Mediterranean type may be discerned. It differs from the second chiefly in that the nose is unusually long and convex, and the skin is lighter.

The second of the main racial elements is a broad-headed strain which shows some affinities with the groups of brachycephalic peoples to the west—the Alpines, Dinarics, and Armenoids. In general, this type varies in stature from short to medium, and in skin color from light to dark brown; the head is broad and sometimes high; the nose is prominent and in some cases convex; and the hair is straight and usually abundant on face and body. One group of broad-headed people, perhaps allied to brachycephalic peoples in southern Arabia, appears on the west coast in Gujarat and Maharashtra, in the Kannada-speaking areas of Mysore, and in the Tamil-speaking areas of Madras. Another, somewhat different type may be observed in Bengal, Orissa, Mysore, and Madras. A third variant of this type, the Parsis in Bombay State, appears to be related to the Syrians and Armenians.

It is a reasonable assumption that both the Mediterranean and the broad-headed strains may be traced to groups of people who originally entered the subcontinent from the west, and the same is true of a third major element in the population. Like the Mediterranean strain, this type is dolichocephalic (long headed), but the head is larger. A tall stature, a long face, a straight and narrow nose, and light skin are other distinguishing characteristics. The dolichocephalic type occurs among the upper castes in northern India and here and there in western India, usually mixed to some degree with other strains. The term "Nordic," which is given to this type, indicates its broad affiliations.

The fourth main strain, a Mongoloid element in which the head varies from long to medium and the skin from light to dark brown, predominates along the northern borders of India and

among the tribal peoples of Assam. Typically, the stature is medium; hair is scanty on face and body; the face is short with prominent cheekbones; and the eye sockets are slanting, although the epicanthic fold, which gives a characteristic slitlike appearance to the eye, is not marked and occurs less frequently than among other Mongoloid peoples.

Two other major strains have been identified. One of these, thought to represent the earliest inhabitants of India, is the Negrito. The primitive peoples of the Andaman Islands belong to this group, but only a few slight traces remain in the population of the mainland. A stature of less than five feet and frizzly hair are the chief distinguishing features of this racial group, and individuals with frizzly hair are found today among some of the peoples inhabiting the hills of Kerala. The fact that hair of this type also occurs sporadically among other aboriginal peoples in India suggests that Negritos were at one time widely spread in the subcontinent. The second strain, which predominates among the tribal peoples of central, western, and southern India, and which is an important element in the lowest social strata of the population, is characterized by a long head; short stature; a broad, short face with strongly marked brow ridges; a small, flat nose; wavy to curly hair; and dark to black skin. Because of certain resemblances between people of this type and the Australian aborigines, it has been termed proto-Australoid.

Analysis in these terms makes it clear that the modern Indian population is a composite one, that considerable local variation exists, and that the upper classes are to some extent different in physical type from the lower social strata. The classification of the Indian population as a whole presents a problem for the solution of which adequate data do not as yet exist. Using an approach to the problem of classification based on blood grouping, the biochemists William C. and Lyle G. Boyd point out in the *American Journal of Physical Anthropology* (vol. 12, no. 3, pp. 393-405, Philadelphia 1954) that while there are serological resemblances between the peoples of India and Pakistan and Europeans, the differences (particularly the high frequency of the B blood group in the Indian and Pakistani population as compared with the European) appear to be too great to warrant the classification of Indians and Pakistanis with Europeans as a single racial group. Indians and Pakistanis share some similarities with the Asiatic race, as defined by blood grouping, but are nevertheless to be distinguished from it. The Boyds suggest that the peoples of India and Pakistan be classified as a separate racial group to which they give the name Indian or Indo-Dravidian, "to be regarded as intermediate between the Asiatic race and the European race, but closer to the European." Such a classification is not at variance with the evidence derived from a study of physical characteristics. On the basis of blood grouping, however, there is not much evidence to show a relationship with the Australian aborigines.

Tribal Peoples.—The tribal peoples of India have not been enumerated as a separate group since India and Pakistan were divided in 1947. Estimates of their numbers vary from 15 million to 26 million, in part because there are no clearly defined criteria for the enumeration of this group, and in part because in many areas it is almost impossible to draw a line between it and the low-

est castes of the Indian population. It is probable that some of the so-called untouchables were originally outside the Hindu social system, eventually came to be a part of it, and there held the place at the bottom of the social hierarchy which they now occupy. The process of assimilation is a continuing one. While they differ greatly from group to group, the tribal folk as a whole inhabit a more restricted world in a spatial as well as an interpersonal sense than other Indians, and their culture generally lacks the complexity and elaboration of the great Indian civilization.

Assam is the homeland of approximately 2.5 million tribal peoples who inhabit chiefly the hilly, forested regions of the state. Although a few tribes practice terraced agriculture, most of them still cultivate by cutting down and burning the jungle growth and sowing seed in the ashes. Every year or so they move on to a new patch of forest. (This method is practiced also by some of the tribal groups in central India.) The tribes of Assam speak a number of different languages, none of which were reduced to writing until Christian missionaries undertook the task in the 19th century. One large group, the Khasis, who speak a language of dubious external relationship, are organized in 25 small states, each with its own chief. Descent is in the female line, and women play important roles in social, economic, and religious life. A number of distinct tribes, the members of which speak Tibeto-Burmese languages and are known collectively as the Nagas, constitute about 97 per cent of the population in the Naga Hills. Formerly they were warlike, and the practice of head-hunting, chiefly for magical purposes, has not entirely died out. Although the Nagas differ not only in language, but in some respects in economic, social, and religious customs, they combined in the 1950's under a single leadership to demand autonomy, and in 1957 the autonomous Naga Hills-Tuensang Area was created within Assam.

Extending in a wide belt across central India are a number of other tribal peoples. The western end of the belt is the home of the largest single group, the Bhils. Some Bhils live in small, scattered communities more or less isolated in the hills, while others are attached as watchmen, menials, or agricultural laborers to villages occupied by members of the general Hindu population. All speak the language, or a dialectal variation of it, common to the area. Farther east, in Maharashtra and Madhya Pradesh, the Gonds, who speak a Dravidian language, form a bloc of about 3 million tribal peoples. Another Dravidian-speaking group, the Oraon, are found on the Chota Nagpur Plateau in Bihar along with a number of Munda-speaking tribes, the most important of which are the Santal, Ho, Munda, and Kharia. Other tribal peoples, some of them at least linguistically related to the speakers of Munda languages, extend throughout the hill country of Orissa. In the entire central belt the tribal peoples are concentrated in the hilly sections, while the more fertile and easily accessible plains are occupied by Hindu castes. Where the two groups have come into contact, the distinguishing features of tribal life tend to give way, and the tribal peoples gradually become assimilated; in the hills, cut off from extensive contact, the tribal peoples maintain a distinctive way of life.

This is also the pattern in south India. Here and there in the heavily forested hills of Kerala,

in Madras, and in Andhra Pradesh are small, scattered tribal groups who speak the language of the area but live a primitive life with an economy based on food gathering and the sale of forest products. The Chenchus of Andhra Pradesh, who number in all about 12,000, include a small group of several hundred who live a very primitive, seminomadic life in the hills of Amrabad. Their principal diet of wild tubers and fruits is supplemented in some cases by grain, which they cultivate in small patches; they have not adopted the plow, and their chief implements are the digging stick, ax, bow and arrow, and knife. Ceremonial life is simple in the extreme, and religious ritual is undeveloped. The Todas present another contrast to the typical south Indian way of life. Few in number, they are found in the Nilgiri Hills of Madras. In physical appearance and in dress they stand out from the surrounding population, and the architectural style of their temples and dwellings is distinctive and probably archaic. Their economic and religious activities, closely interwoven, center around their herds of buffalo. They are one of several matrilineal peoples in south India and practice polyandry.

3. THE LAND AND ITS RESOURCES

Physiography and Geology.—Three major earth features exist in the Republic of India: (1) the stable massif of ancient crystalline rock which forms the Indian peninsula; (2) the northern mountain belt in which the rocks have been folded, faulted, and uplifted in the Himalayan system; and (3) the alluvial lowland of the Ganges and other Himalayan rivers, resulting from the filling of a great structural depression between the peninsular block and the extrapeninsular mountains.

Peninsular Massif.—The peninsular massif is a basement complex of Precambrian granite and associated Archean metamorphic rocks (gneiss and schist), which are estimated to be 500 million to 2,000 million years old. Wherever these formations outcrop, there are plateaus with undulating surfaces or hills with broad, rounded summits seldom rising more than 3,000 feet above sea level. Except along the coasts and in the largest interior valleys, the surface elevation is over 1,000 feet above sea level. Two high granitic masses are found in the south—the Nilgiri Hills, which rise to more than 8,500 feet; and the Anaimalai Hills, which reach over 8,800 feet. In the central, western, and eastern parts of the peninsular uplands the most prominent hilltops rise only 4,000 to 5,000 feet above the sea. The one portion of the Indian peninsula that can be described as a tableland is the Deccan, in the northwest, where many successive lava flows spread in the Tertiary period over an area measuring approximately 400 miles from east to west by 500 miles from north to south in Bombay State and Madhya Pradesh. Here the typical landscape features are the dissected remnants of the high lava beds, which form tabular ridges and terraces. The lava (also called traprock) is of basaltic composition and was emitted from fissures in the earth's crust without explosive eruptions, hence without the forma-

The vast ranges of the Himalaya, seen from a high mountain pass on the border between Sikkim and Tibet.

tion of volcanic cones.

The configuration and drainage of the Indian peninsula have been influenced by vertical faulting and tilting of the massif. The part south of 21° north latitude has been tilted eastward and presents bold heights to the west along the line of faulting which determines the coast of the Arabian Sea. Three major rivers—the Godavari, the Krishna (Kistna), and the Kaveri (Cauvery)—start within 50 miles of the Arabian Sea and flow generally eastward for distances of 475 to 900 miles to the Bay of Bengal. The Arabian Sea margin of the peninsular uplands is an uninterrupted escarpment which forms a low mountain range known as the Western Ghats, a name derived from many passes (ghats) leading across the water divide and down to the coast. On the eastern side of the peninsula are several distinct ranges of hills or low mountains, collectively called the Eastern Ghats. These east coast highlands are interrupted by large breaks or deep water gaps through which pass the three major rivers as well as the Mahanadi and other rivers in Orissa. The east coast is bordered throughout by an alluvial plain, which is broadest where the deltas of the east-flowing rivers have been built. On the west coast below the main scarp of the Ghats, which is 30 to 50 miles inland, continuous alluvium is found north of Bombay Island and in Kerala.

The northern part of the peninsular massif is tilted northward, and its drainage is toward the Ganges River. The Vindhya Range of Madhya Pradesh is the dissected southern edge of this northern block. At its southern foot is a narrow east-west valley formed by downfaulting and drained through the Narmada River into the Gulf of Cambay and the Arabian Sea. The parallel Satpura Range to the south is a structural uplift, and the valley of the Tapi River is in part another downfaulted structure, also draining westward. The massif, which is capped with limestone and sandstone as well as with basaltic

lavas, ends in a ragged border along the margin of the Gangetic Plain and the Thar Desert of western Rajasthan. The northernmost part of the peninsular massif is formed by Lower Paleozoic and Precambrian sedimentary rocks (shales, limestones, and sandstones), folded and partly metamorphosed, worn by prolonged erosion, and appearing as ranges 2,000 to 3,000 feet in height known as the Aravallis, which trend from south-southwest to north-northeast in Rajasthan and terminate at Delhi in the Ridge. In the northeast the undulating surface of the massif known as the Chota Nagpur Plateau descends from southern Bihar to West Bengal and ends in the lava-capped Rajmahal Hills about 175 miles north of Calcutta.

Small outlying areas with structure and rock formations similar to those of the Indian massif are separated from it by alluvial veneer. To the west are the low-lying lava formations of the Kathiawar peninsula and the "island" of Kutch in northern Bombay State. Here and in the Thar Desert are found also the eroded remnants of various sedimentary rock formations, varying in age from the Upper Paleozoic to the Jurassic. To the northeast in Assam are the maturely dissected gneissic Garo, Khasi, and Jaintia Hills and the Mikir and Rengma Hills, separated from one another and the peninsular massif by alluvial plains and abutting the younger folded mountains of Tertiary rock formations along the Burma frontier.

Northern Mountains.—The great mountain wall which towers along the northern border of India is in almost every respect the antithesis of the peninsular massif. The rugged ridges and narrow V-shaped valleys of the Himalayan chains are features resulting from the rapid uplift of the rocks and the vigorous erosion processes prevailing here. The unusual height of the peaks in the Himalaya and Karakoram ranges results from the mountain-building forces that have been working here during the last great geologic era—the Cenozoic (Tertiary and Quaternary periods)—that is, during the last 60 million years. The folding and thrust faulting of sedimentary strata observed in the Himalayan mountain system indicate that horizontal compression has been exerted in the earth's crust, throwing up gigantic rock waves against the buried northern margins of the Precambrian massif. Fossils of marine origin found embedded in the rocks on the northern flanks of the highest range at elevations of 14,000 to 18,000 feet prove that these rocks were laid down in a sea existing in the Tertiary period over what is now the Tibetan plateau. The mountains are believed to be continuing to rise, the severe earthquakes of the region being symptoms of this active growth.

Both the rock structures and the surface configuration of the Himalaya show trend lines transverse to the direction of tectonic forces. The Great Himalaya, with some 40 peaks in India and Nepal between 25,000 and 29,000 feet above sea level culminating in Mount Everest (29,028 feet), forms a 1,500-mile arc from the Indus River on the west to the Brahmaputra on the east. The core of this range consists of granite and gneiss of unknown geologic age. The Lesser Himalaya, a parallel belt 50 to 80 miles wide which rises to heights of 7,000 to 15,000 feet above sea level, is formed by a series of recumbent folds overthrust from the north. This belt is composed of metamorphic rocks and unfossiliferous sedimentary rocks which are probably of the same origin as

the Precambrian and Paleozoic rocks of the peninsular massif, and which may actually represent the buckled edge of the massif itself. The foothill belt of the Siwalik Range, generally 2,000 to 3,500 feet above sea level and 10 to 15 miles in width, is developed in the youngest Miocene and Pliocene rocks involved in Himalayan orogeny and forms a distinct physiographic region of low, slightly folded ridges bordering the Indo-Gangetic plains.

To the north, paralleling the Great Himalaya, are ranges 20,000 to 25,000 feet high in Kashmir and Tibet. The Karakoram, lying 100 to 150 miles north of the western portion of the Himalaya, is the only range to equal the latter in height. Indeed, the crest of the earth waves in

this western portion of the extrapeninsular mountain system is found in the Karakoram, where the world's second highest peak, K², reaches 28,250 feet above sea level.

Flanking the Himalaya on the east is a succession of arcuate ridges turning southward from a hinge point in upper Assam along the frontiers of China to the Arakan Yoma in Burma. The structural trend of these simple folded mountains of Lower Tertiary and Cretaceous sedimentary rock formations is northeast and southwest in the rugged Patkai Range and Naga Hills (9,000 to 12,500 feet above sea level) and north to south in the Manipur Hills (rising to 8,400 feet above sea level) and the Lushai Hills (reaching over 5,500 feet).

The Republic of India: principal cities, products, and resources.

The rivers of the Himalaya tend to be entrenched in narrow valleys, some of which are cut directly between the highest peaks, and many of the sources of the largest rivers, such as the Sutlej, Indus, and Brahmaputra, are beyond the Great Himalaya in southern Tibet. Only north of the Indus in the Karakoram and south of the Brahmaputra in the Assam frontier ranges do the highest ranges of peaks form the water divides between these rivers and the rivers of interior or southeast Asia. A few intermontane basins exist within the extrapeninsular mountain belt in which Pleistocene lake-bed sediments form tracts of level land. The most prominent among them are the Vale of Kashmir, the Nepal Valley, and the Manipur Basin.

See also *HIMALAYA, THE*.

Alluvial Lowland.—The third great physiographic division is the lowland formed by the contiguous plains of the Ganges, Indus, and Brahmaputra rivers, development of which was contemporaneous with the building of the Himalaya. As the mountains were uplifted, the depressed belt to the south was gradually filled by detritus brought by the streams from the mountains, burying the hard rock under many thousands of feet of unconsolidated material. The Ganges (Gangā) and its Himalayan tributaries, the Jumna (Yamunā), Ghaghra (Gogra), and Gandak, flow southeastward obliquely to the main stream near the southern margin of the plain. Only the Kosi flows directly southward from the foot of the mountains in Nepal. The Ganges and Jumna receive relatively little flow or sediment from their southern tributaries, the Chambal, Betwa, and Son. The Punjab plain slopes generally southwestward from the foot of the Himalaya, and across it flow the five Indus tributaries, the Sutlej, Beas, Ravi, Chenab, and Jhelum, which enter Pakistan immediately upon leaving the mountains or shortly thereafter.

The stoneless surface of the plains appears to the eye to be perfectly flat, but local variations in relief and drainage introduce important modifications. Conspicuous eroded bluffs occur within a few miles of the major rivers in the southern half of the Gangetic Plain, indicating that alluvial material is being removed and redeposited downstream. All the rivers of the Indus and Ganges systems have become slightly incised below the surface in most parts of the plains and are capable of freely depositing fresh alluvium only in the fans, where they debouch from the mountains, and in the deltas near the coast. Most of the surface is therefore made up of natural terraces of old alluvium, not subject to flooding. The Brahmaputra in Assam is an immense braided stream, averaging a mile in width and much more in flood. The gradient is extremely low, and the river has a larger volume than either the Ganges or the Indus at high water.

The Thar Desert, which lies in Rajasthan adjacent to the plains of the Indus, can be considered part of the alluvial region, although the surface is broken by numerous rocky projections and by wind-drifted sand ridges. The desert is traversed by a prehistoric river channel, the Ghaggar, traceable 600 miles from the Punjab to Sind, by means of which the water from either or both the eastern Indus or the western Ganges affluents once reached the Rann of Kutch. Today the Rann is a sterile, salt-encrusted marsh, cut off from the sea and inundated briefly during the summer monsoon season.

Mineral Resources.—India is only moderately well endowed with coal, deficient in petroleum, but rich in certain metallic ores and mica. It is in the peninsular massif that most of the significant deposits are to be found.

Of the conservatively estimated reserve of 50 billion tons of coal, 98 per cent occurs in a series of fault basins containing beds of Lower Gondwana (Paleozoic) age. The most productive mines are in the Damodar Valley in the Chota Nagpur Plateau of southern Bihar and adjacent West Bengal. Other coalfields exist chiefly in the faulted belts of the Mahanadi and Godavari valleys, Madhya Pradesh, Orissa, Bombay State, and Andhra Pradesh. About 99 per cent of India's annual coal output of approximately 45 million tons is derived from the Lower Gondwana deposits of the peninsula. The balance is obtained from low-grade Tertiary formations located in the piedmont plains of northern Bengal and Assam. Much of Gondwana coal is of high-grade bituminous quality, and it is possible that there may be as much as 80 billion tons of all grades available, but relatively little is of coking quality.

There is petroleum in the Tertiary formations of upper Assam, but the small oilfields located here produce only about 5 per cent of the nation's annual consumption of 7 million to 8 million tons. Hence, India is dependent upon Burma, Indonesia, and the Persian Gulf countries for most of its petroleum requirements.

India's iron reserves are unquestionably among the richest in the world. Ore of highest quality occurs in large deposits capping the hills in the northeastern peninsular uplands. The hematite bodies of Orissa and Madhya Pradesh, which yield 60 to 65 per cent metallic iron, are estimated to contain at least 4 billion and possibly 8 billion tons of ore. There is also good hematite in Mysore and magnetite ore in Madras. The country produces between 5 million and 6 million tons of iron ore annually, and the iron and steel industry is developing rapidly.

Deposits of other metallic minerals and of mica are associated with the Precambrian and Archean crystalline rocks in three general areas: (1) the northeastern portion of the peninsular massif in southern Bihar, interior Orissa, central Madhya Pradesh, and easternmost Bombay, where the most important workings of manganese, copper, chromite, and mica are located; (2) the southern portion of the massif in Andhra Pradesh, Mysore, and Madras, where gold is most abundant, and where manganese, mica, magnesite, and chromite also are obtained; and (3) the northern portion of the massif in Madhya Pradesh and Rajasthan, where lead-zinc ore, mica, and manganese are worked. India ranks as a foremost source in world trade of mica and manganese but is unable to supply domestic requirements for copper, lead, and zinc.

The black beach sands of the southern coasts, particularly in Kerala, yield ilmenite, from which is obtained titanium, useful as a white pigment; and monazite, from which the heavy radioactive metals, thorium and uranium, are derived. India has great fame as a source of diamonds, and it does not appear that all the diamond deposits have been exhausted, although the annual output is small. The country is well endowed with bauxite, limestone, and industrial clays and sands, and has made a good beginning in the manufacture of aluminum, cement, and various ceramic products. Salt, amounting to 3 million tons annually,

is obtained from the evaporation of seawater along the peninsular coasts; from brine springs, wells, and salt lakes in arid or semiarid regions of Rajasthan and Uttar Pradesh; and from rock salt in the northern mountains.

Climate.—Three seasons are recognized in India: the rainy season, the cool season, and the hot season. The rainy season (June to October) is a time of high temperatures and abundant moisture, brought by the summer monsoon, upon which the agriculture and the very life of India's people largely depend. The cool season (November to February) is a time of the continental monsoon and prevailing dry weather except in the northernmost plains and the adjacent mountains and in the extreme southeast coast of the peninsula. The hot season (March to May) is also a time of the continental monsoon and of continued dry weather except in southern Kerala and Assam.

The arrival of the summer monsoon air causes dark clouds to gather and rain to begin abruptly. So distinct is the rise in humidity and the fall in temperature that the Indian Meteorological Department officially records the date of arrival at each of its observatories. But the arrival of the monsoon does not automatically bring water to the parched plains of India as though a garden sprayer had been turned on. The largest and most reliable precipitation is received on the windward sides of mountains. The western slopes of the Ghats are extremely rainy because they stand almost at right angles to the path of the tropical maritime air, coming directly west across the Arabian Sea. The Assam hills and the eastern Himalaya are also exposed fully where the recurring monsoon blows against their southern slopes. At least 75 inches of precipitation (June to October) are received throughout each of these mountainous areas. The most intense precipitation (100 to 200 inches) does not occur on the coast or at the foot of the mountains but at intermediate elevations, where the instability levels are reached in the ascending air at 2,000 and 3,000 feet in the Western Ghats and along the ranges east of 88° east longitude at levels between 3,000 and 5,000 feet. Cherrapunji, at an elevation of 4,300 feet in the Khasi Hills south of Shillong, Assam, is perfectly situated for the full orographic effect, receiving an average annual precipitation of 426 inches, one of the two highest recorded averages in the world (the other is 476 inches, in Waialeale, Hawaii).

Rainfall occurs in areas of low relief chiefly because the sun heats the ground each day, producing convectional updrafts, cumulus clouds, and light, scattered showers. A large share of the 30-to-60 inch precipitation (June–October) in the northern plains and in the interior valleys and hill country of central and northeastern peninsular India is of this simple convectional type. On the leeward, east-facing slopes of mountains and in the interior plateaus and valleys of peninsular India, precipitation is only 10 to 30 inches during the rainy season. The maritime air is no longer saturated because of the release of so much moisture on the windward slopes of the mountains and because of adiabatic heating, which occurs as the air descends the leeward slopes. Two dry rain shadows therefore exist within tropical India: (1) the large area behind the Ghats which occu-

pies the interior parts of Bombay and Andhra Pradesh, as well as much of Mysore; and (2) the region east of the Nilgiri and Anaimalai Hills in southern Madras.

North of 20° north latitude, however, rain shadows disappear because of the easterly lows which traverse central and northern India three or four times a month from June to September. These lows appear between 20° and 25° north latitude, where the southwest winds of the monsoon are recurving as southeast winds at the head of the Bay of Bengal. As a low migrates to the west, the precipitation gradually decreases because dry, continental air enters its vortex in increasing amounts, and the source of the moist air becomes progressively more distant. By the time the low has reached Rajasthan, continental air has become dominant, and precipitation is meager south and west of Delhi. This circulation pattern of maritime air currents in these lows accounts for the copious rainfall over the lowlands east of 78° east longitude and north of 20° north latitude, and also adds to the intensity of orographic rainfall in the eastern Himalaya.

Dry continental air masses gradually spread over northern India during September and October and dominate all of South Asia during the ensuing cool season from November to February. Reduced insolation during the Northern Hemisphere winter allows the land to cool, and atmospheric pressure rises slightly higher over the land than over the adjacent warm seas. The combination of cool, dry air at the surface and stable dry air aloft produces the cloudless, sunshiny weather prevailing at this season. The mean January temperature remains above 70° F. in southern India and above 60° F. in the interior lowlands as far north as Delhi. Beyond 28° north latitude the monthly mean for January falls to about 55° F., and light frosts occur on the plains, while in the Himalayan foothills the average January temperatures decrease to 32° F. at altitudes over 5,000 to 7,000 feet.

Not everywhere is the weather dry throughout the cool season. During October and the following two or three months the wet monsoon is recurving in the Bay of Bengal, bringing the year's heaviest rainfall to the rain-shadow areas east of the Ghats. Weak easterly lows continue to form in the retreating maritime air over the water and move toward the east-facing coasts. Occasionally violent tropical cyclones of the hurricane type appear drifting from the east or southeast over the Bay of Bengal or the Arabian Sea and affect the coasts of Bengal and peninsular India. The rainfall of the retreating monsoon is confined mostly to the east coast of India south of 15° north latitude, where November and December are the rainiest months of the year.

In extratropical India, November marks the beginning of a season of occasional rain, brought by the westerly lows or winter cyclonic storms of the middle latitude type, the so-called western disturbances. As frequently as four or five times a month (December to April) these cyclones cross the country, generally north of 30° north latitude. The frosts on the plains of extratropical India occur during the nights following the passage of westerly lows, when cold continental air from the plateaus of southwestern Asia has invaded the plains. In the high basins and mountain valleys minimum temperatures of 0° F. are experienced under clear night skies and the influence of local air drainage during the calms following the pas-

sage of the cyclones. The cool season precipitation, which amounts to less than 5 inches in the Punjab plain and to as much as 10 or more inches in the adjacent mountains, is derived from the maritime air brought inland by the lows. The high ranges of the western Himalaya and the Karakoram become blanketed under heavy snow and are believed to receive most of their annual precipitation at this season.

The northward shift of the sun's vertical noonday rays and the increasing length of the days during March, April, and May cause the belt of most intense solar radiation to move progressively northward over the tropical part of India and finally, by June, into the extratropical part. The temperatures therefore become progressively higher, and occur progressively farther north during the hot season. In March the highest daytime temperatures of about 100° F. are in the interior Deccan of Bombay, in April the highest daytime temperatures of 110° F. are in Madhya Pradesh and northern Bombay, and in May the highest daytime temperatures of 120° F. are in Rajasthan. Almost equally high temperatures are recorded in the northern interior plains of Uttar Pradesh and the Punjab in June before the arrival of the summer monsoon. The afternoon hours at this season become so intolerably hot that human activity ceases until sunset approaches. Both men and beasts seek shelter from the burning sunlight and look out upon the dry, brown earth, awaiting the arrival of the life-giving monsoon.

See also RAINFALL—*Distribution of the World's Rainfall*.

Vegetation.—The distribution of wild vegetation in India is manifestly related to climatic conditions, but because of the depredations of man there are few areas where "natural" vegetation exists, or where the unhampered growth of plant cover fully reflects climatic potentialities. A large fraction of the area not actually under cultivation or in fallow supports only a scanty growth of low scrub or thin grass because of frequent lopping of branches for firewood and continued browsing by livestock. Much mountain or hill land not under permanent cultivation has been repeatedly cleared by burning for shifting cultivation. The three most important forest zones are (1) the evergreen broadleaf, (2) the deciduous broadleaf, and (3) the thorn scrub. The distribution and composition of these forests is controlled chiefly by the supply of moisture. Temperature has a secondary influence except in the extrapeninsular mountains above an altitude of 3,000 or 4,000 feet, where the subtropical, temperate, and alpine forest zones exist.

In general, an annual rainfall of 80 inches is necessary to support the dense stand of large, soft-leaved trees which constitutes the evergreen broadleaf forest. While as little as 50 inches will support evergreen growth if the rains are well distributed throughout five or six months from May to October, as much as 200 inches are necessary under unfavorable conditions, such as steep slopes or dry soil. The fully developed tree canopy consists of a variety of species which retain their foliage throughout the year. The dominant species include several belonging to the family Dipterocarpaceae. The understory and shrub growth are scanty, but there are many lianas and epiphytes. Where the rainfall is less than 80 inches annually, certain deciduous broadleaf trees may be present in the top canopy, forming a semi-evergreen forest type which becomes progressively

more prevalent toward the dry margins of the zone. One part of the evergreen broadleaf zone is located along the western coastal lowland of India and on the rainy windward slopes of the Ghats. The largest area of this vegetation spreads from the hills of East Pakistan into the Assam lowlands and hills.

The deciduous broadleaf forest zone is located in the hills and plateaus of central and southern India, where annual rainfall of 35 to 80 inches occurs almost exclusively during the four or five rainy months from June to October. The deciduous character of the dominant tree species is a response to the long period of dry weather. The branches of the trees forming the top canopy gradually become bare as the soil dries and the hot season approaches. The understory is composed of small evergreen broad-leaved trees and bamboos in the moist deciduous type of forest, where the rainfall is 60 to 80 inches. Teak (*Tectona grandis*) and sal (*Shorea robusta*) are typical species of economic value in the moist deciduous forest areas of the uplands in peninsular India, where the natural growth is least disturbed by man. Dry deciduous forest is prevalent where the rainfall is as little as 35 or 40 inches. Even the understory trees become bare in the dry season. Shrubby undergrowth is often present, and sometimes there is grass, which tends to become more highly developed under burning and shifting cultivation. In places a parklike landscape may result, but no tropical savanna type of vegetation is widespread in India. The term "jungle," derived from the Hindi word *jāṅgal*, is commonly applied in India to these tropical deciduous forests and to the thickets into which they degenerate under the inroads of woodcutting, shifting cultivation, and grazing.

Thorn scrub is associated with the semiarid climatic areas of northwestern and peninsular India, where the annual precipitation is between 20 and 35 inches. The fully developed forest under this climate consists of an open canopy of thorny hardwood species, predominantly of the genus *Acacia*, which have short boles of 20 to 30 feet and low branching crowns which rarely meet. There is an ill-defined lower story of spiny xerophytic shrubs and sparse grass which does not completely cover the ground even during the rainy season. The thorn scrub forest is replaced by xerophytic shrubs and fleshy *Euphorbia* cactus where the trees are destroyed by woodcutters and livestock.

Soil Zones.—The varied characteristics of soils in the vast alluvial region of northern India depend primarily on the texture and fertility of the parent material. Yet on the terraces of old alluvium above flood levels in the warm and humid climatic zone there is evidence of leaching and laterization associated with the subtropical climate. Effects of soil formation on terraces in the dry climatic zone of northern India tend to produce profiles somewhat resembling the chestnut and brown steppe soils of middle latitudes. The most important effects of soil formation in alluvium under the arid and semiarid climates are the subsoil lime concentrations, due to leaching, and the salt encrustations, resulting from the evaporation of ground water in low spots. Some alluvial areas are covered with peat where drainage is impeded.

In the Indian peninsula well-developed zonal soils are spread over the undulating, rolling, or hilly terrain. Here the outstanding zonal soils belong in two groups: (1) dark-colored regur,

and (2) yellow or red lateritic soils and the true laterite of reddish brown color. The regur soils are spread over approximately 200,000 square miles of territory between 73° and 80° east longitude and 15° and 25° north latitude, mainly in Bombay and Madhya Pradesh. They also occur south of 15° north latitude in outlying areas in Mysore and southern Madras, and east of 80° east longitude in the northeastern peninsular uplands. Soils of this group are composed of dark brown or black clayey material which expands during the rainy season and contracts during the dry season. Regur soils are commonly found over parent material derived from the basaltic Deccan lavas or on alluvium from the same source, and their color has often been ascribed to the basic minerals present in the parent rock. But regur is also developed from bedrock of sedimentary origin, such as limestone, shale, and sandstone; from calcareous clays; and even from metamorphic slates and gneisses. Generally the rocks upon which all of these dark-colored soils are developed are basic in character and low in quartz (silica) content, and form slowly permeable clays upon weathering. The lime (calcium) content of the regur soils also is high. Although the dark color is now proved to be due to finely divided organic matter rather than to the color of the parent rock, the organic matter content (less than 1 per cent) is very low in comparison with the black chernozem and dark brown prairie soils of middle latitudes.

Wherever peninsular India receives more than 60 inches of annual precipitation, there are lateritic soils or laterites. The lateritic soils vary from the deep red clayey soils of the valleys to the light red and yellow gravelly or loamy soils of the hills and lower slopes. Indurated laterite crust is found on hilltops or mountains and on old alluvial or marine terraces. Lateritic soils are deficient in nitrogen, phosphorus, and humus and are generally low in potassium and lime, but are rich in hydrated aluminum and iron oxides. The red and yellow soils commonly contain more siliceous material than true laterite does. The latter forms evidently as the end product of the leaching out of siliceous material and of almost all other mineral compounds except the oxides of iron and aluminum. It becomes an inert, honey-combed mass of iron and aluminum clay through which water passes without causing much runoff or erosion.

Land Utilization.—The most significant features of land utilization in India are (1) the large fraction of the area suitable for agriculture, and (2) the extent to which the good land has been brought under cultivation. About 11 per cent of the surface area of the country is made up of mountains over 7,000 feet in elevation, almost all of which are too steep or too cold for agriculture. Another 18 per cent is hill land between 1,000 and 7,000 feet above sea level, three quarters of which are too steep to farm. Plateaus of relatively low relief between 1,000 and 3,000 feet form 28 per cent of all land in India, all but a quarter of which is topographically usable. In the lowlands of less than 1,000 feet in elevation, which comprise 43 per cent of the total area, only 1 acre in 20 is unusable because of roughness of topography. Altogether, 66 per cent of the land is topographically usable, but climate imposes limits of aridity which reduces cultivation to about 40 per cent of the total area.

The total cropped area is about 350 million

Kulwant Roy

A romantic view in the Vale of Kashmir.

acres. While this amounts to less than 1 acre per capita, it means that among the large nations of non-Soviet Asia, India is one of the best endowed with agricultural land. About 52 per cent of the village land area classified (77 per cent of the total area of India) is in crops or fallow. Wasteland and land devoted to urban or village settlement and other nonagricultural uses comprise 16 per cent of the area classified; forest land, 15 per cent. The remainder, 17 per cent, is made up of village pastures and firewood groves, jungle scrub and bamboo, private forests, and cultivable wasteland. Most of this land is submarginal, however, and cannot be brought under cultivation. The agricultural land may be divided into three major categories on the basis of the crops grown and the methods of farming: (1) wet cultivation, (2) dry cultivation, and (3) irrigated cultivation.

Wet cultivation prevails in the alluvial lowlands in tropical or subtropical latitudes with 40 inches or more precipitation in eastern and southern India. The leading crop is rice, which occupies one half to two thirds of the area planted annually except in the Gangetic Plain of Bihar and eastern Uttar Pradesh and on the coast of Kerala, where it accounts for about 40 per cent of the planted area. Winter wheat and barley (in the Gangetic Plain), corn, and various oilseeds are the commonest secondary food crops in the areas of wet cultivation, but rice is ideally suited to the naturally inundated plains wherever rainfall of 60 inches or more is received. Irrigation is necessary for rice in the eastern coastal deltas and interior lowlands, where the rainfall is less than 60 inches. Rice produces an average of 750 pounds of grain per acre in India, or more than any other grain, and it supports the densest rural population—600 to 1,000 or more persons per square mile. Sugarcane and jute are important as sources of cash income in the alluvial areas of northern and eastern India, and tobacco is a locally significant cash crop in Bombay and Andhra Pradesh. Coconuts are produced commercially on the coasts, especially in Kerala. Coffee in Madras, tea in Madras, northern Bengal, and Assam, and rubber in Kerala are commercial plantation crops produced on the red lateritic soils of the terraces and uplands adjacent

to the flood plains under wet cultivation.

Dry cultivation prevails in the uplands and interior valleys within the peninsular massif and along the margins of the Indo-Gangetic plains. The climate in general is semiarid with 18 to 35 inches of rain, but dry cultivation extends into the desert zone of Rajasthan, where rainfall is as little as 15 inches, and into central India, where as much as 40 inches are received. The fertile regur soils are widespread here, but water supply is insufficient to irrigate much land adequately. The necessity of following to conserve moisture in the subsoil withdraws one tenth to one third of the arable land from crop production each year. Rice production is unimportant, though not excluded, and wheat is important within the region of dry cultivation only in north central India. Sorghum and the lesser millets are the dominant subsistence crops, though poor substitutes nutritionally for rice and wheat. Grain sorghum, called jowar, durra, or *cholum* in India, is a major crop throughout the region of dry cultivation and is the food grain second in rank after rice in acreage and production in the country as a whole. Bulrush millet (*Pennisetum typhoides*), called bajra or cumbu in India, has somewhat lesser moisture requirements than sorghum and is concentrated in the drier parts of the Deccan and Rajasthan. Finger millet (*Eleusine corocana*), called ragi (raggee) or *marua*, and another millet called *kodo* (*Paspalum scrobiculatum*) are the most tolerant of drought. Altogether, there are nearly three dozen species of lesser millets which will grow under conditions where wheat or rice would fail. Oilseeds, particularly peanuts, sesame, and castor seeds, are produced under dry cultivation. Cotton growing is widespread and is the chief source of cash income. Cotton acreage is concentrated on the black regur soils of the northern Deccan, but the yield and quality are not as high as on the northern Bombay coast. In general, agricultural production is less intensive under dry cultivation than under wet cultivation, and the population density averages about 200 to 400 persons per square mile or less.

Irrigated cultivation is the basis of agriculture in an extensive belt in the semiarid plains of Rajasthan and the Punjab and in the upper Gangetic Plain in Uttar Pradesh. Irrigation is practical because of the abundance of water from the melting winter snows and the heavy monsoon rains in the Himalaya. Much water is brought to the alluvial terraces through modern systems of diversion dams, canals, and ditches. The ground water table is close to the surface and is tapped by means of hand-dug wells or tube wells in order to irrigate fields not reached by canals. Flood-plain irrigation is commonly accomplished from wells or seasonal inundation canals. These irrigated plains of northern India support a moderately dense rural population, ranging from 100 to 600 persons per square mile, and form the most prosperous agricultural areas.

In the northern irrigated tracts winter wheat is the most widespread subsistence and cash crop. Barley is a second winter grain, grown for subsistence. Maize, sorghum, and bulrush millet are the most important subsistence crops produced in summer, often not in irrigated fields because the water must be conserved for cash crops. Cotton of better quality than that of peninsular India is grown, and commercial sugarcane has gained in importance. Oilseeds, especially linseed and rape-

seed, are locally significant. Legumes and fodder crops are relatively more important than anywhere else in India.

Irrigated cultivation also is widespread in peninsular India. It is intensively developed along the east coast in Madras and Andhra Pradesh, where one third of the area under crops is watered artificially in some manner. Diversion dams and elaborate canal systems ensure the crops in the rich deltas of the Kaveri, Krishna, and Godavari rivers. Elsewhere in the alluvial lowlands and in upland valleys of the Deccan innumerable storage reservoirs have been created by excavation or building with dams. Water reaches the fields by means of primitive lifting devices, by ditches, and by seepage underground. The crops grown are rice, where the water supply is abundant, and the typical dry crops of the region elsewhere.

In the country as a whole an area of almost 58 million acres, or 16 per cent of the total cropped area, was under irrigation in 1956, and planned development called for the addition of 20 million acres. The increase of irrigation was expected to help alleviate the two greatest problems of agricultural land utilization: (1) the high percentage of cropland fallowed each year (about 1 in 5 acres), and (2) the generally low crop yields.

Another Indian agricultural problem is that of animal husbandry. According to the livestock census of 1956, the country has 203.6 million cattle, including water buffaloes, and 94.6 million sheep and goats. In addition, there are horses, donkeys, camels, pigs, and poultry, resulting in a farm-animal density too great for proper feeding. The cows give meager quantities of milk, and because of religious taboos little beef is used.

4. ECONOMIC DEVELOPMENT

INDIA BEFORE 1947

Rural Economy.—The development of the rural economy of India before independence may be divided into three periods: that of pre-British society (to 1793), the period in which new land systems were introduced (1793–1850), and that of the spread of commercial agriculture (1850–1947).

Pre-British Structure of Indian Society (to 1793).—The outstanding feature of the economy of India before the advent of British power was the self-subsisting and self-perpetuating character of its typical unit, the village. India's villages functioned as little worlds of their own. The only outside authority which they acknowledged was that of some local princeling who in turn might be subordinate to a distant overlord. The chief sign of submission to that authority was the payment of a share of the village crops.

Within the village social and economic relationships were governed by customary patterns and conventions of great antiquity. The cattle were tended and the soil was tilled by peasants whose fathers had been cultivators and whose sons would take their places when they came of age. Cloth for the garments of the peasants generally was spun and woven by families whose ancestors

had been weavers long beyond the living memory of man. The other crafts were carried on by families which in effect were servants of the village. Their occupations passed on traditionally from father to son: the blacksmith, potter, and carpenter, who made and repaired the implements and utensils of the village; the silversmith, who made the village jewelry; and the oilseed presser. For their services these craftsmen received a regular stipend from the crops of the villagers. In some areas hereditary servants and slaves attached to peasant households performed both domestic and agricultural duties.

The village itself consumed most of the raw materials it produced. Its needs for handicrafts were satisfied by the craftsmen associated with the village. It was this tight union of agriculture and hand industry which made the village independent of the outside world except for a few necessities like salt and iron. The share of the crops which went to the local magnate and moved on from him in a diminishing stream upward to the highest political overlord sustained the structure of government and provided subsistence for the urban population. As the local chiefs often constituted a rallying point against the center, some emperors and kings tried to weaken their power by collecting the land revenue without their participation. In their stead they created tax farmers or operated through subordinate revenue officials.

With the exception of pilgrimage centers, India's towns and cities generally were little more than headquarters for the top political overlords or imperial courts. The industries which were carried on in these cities were of two classes: those which met the minimum wants of the urban population, and those which provided mainly luxury goods for the upper classes or implements of war for the army. Economically, the cities had a one-way relation with the countryside, taking foodstuffs as tribute but supplying virtually no goods in return.

This was the structure of Indian society which the British found between 1750 and 1850 as they conquered one part of India after another. The basic land relationships were rooted in custom and usage rather than in statutes, legal cases, and court procedures. So long as the peasants turned over to the local potentate his customary tribute and rendered him the usual services, their right to till the soil and reap its fruits was taken for granted. Local rulers who repeatedly abused this right were considered oppressive; if they persisted, the peasants fled to areas where the customs of the land were better respected. As land was still available for settlement and labor was not too cheap, local chiefs had to be careful lest they alienate the villagers.

The British conquest of India through the agency of the East India Company led to the most drastic changes in the Indian way of life of which we have record. The most fundamental of these changes was the disintegration of the older structure of the village community, partly as a result of new land systems, and partly as a result of the spread of commercial agriculture.

Introduction of New Land Systems (1793-1850).—In making arrangements for collecting land revenue in the areas of India which they conquered, the British were primarily concerned with securing the largest possible amount. For it was basically from these sums that British conquest and consolidation were financed. Two

major types of land revenue systems were devised. In Bengal and adjacent areas, beginning in 1793, the British converted the tax farmers and revenue collectors into private landlords, granting them some of the rights of private property in the land. This was done on condition that the new landlords would raise greatly enhanced revenues from the cultivating peasants and pass the bulk of these revenues on to the state. This land revenue system is known as the zamindari system (Hindi *zamindārī*, from *zamindar*, *zamindār*, or landholder).

An entirely different system was devised for large parts of Bombay and Madras and later applied to areas in the northeast and northwest. Here the British dealt directly with the individual peasants, for thereby they hoped to be able to obtain more revenue than under the zamindari system. Each peasant was recognized as holding the particular plot or plots he occupied, but his right to the land depended on annual payment in full of a heavy money rent to the government. Because it dealt directly with the peasant or ryot (Hindi *ra'iyat*), the new system was called the ryotwari (Hindi *ra'iyatwārī*) settlement. Whereas the zamindari system made the landlords masters of the village communities, the ryotwari system cut through the heart of the village communities by making separate arrangements between each peasant cultivator and the government.

These two systems were the dominant land systems of British India from 1793 to 1947. Under both of them the old body of custom was submerged by the formidable apparatus of law courts, fees, lawyers, and formal procedures. For with the introduction of some of the rights of private property in the land, the purchase and sale of zamindars' holdings were explicitly sanctioned by law. All of this was too much not only for the humble peasants, but also for the new landlords. Most of the latter could not raise the revenues required by the government and soon defaulted or sold out to merchants, speculators, and other sophisticated persons from the cities. The new landlords were interested only in the rents they could squeeze from the land; often they delegated the collection to middlemen who contracted to pay high sums annually. The latter sublet to other classes of middlemen, so that before long the unfortunate peasants of Bengal were supporting an impressive string of middlemen, speculators, and absentee landlords.

The ryotwari system also introduced some features of private property in land. The individual holders were registered and empowered to sell, lease, mortgage, or transfer their right to the use of the land. In contrast to the previous indigenous regimes, which had made more or less elastic demands, the British insisted on prompt payment of the stipulated sums. In cases of default livestock, household property, and personal effects might be attached, and the peasant might be evicted. The new system thus made mobile both the land and the peasant and left the way open for the growth in power of the moneylender and the absentee landlord.

Spread of Commercial Agriculture (1850-1947).—The older rural framework of India, weakened by the new land systems, was shattered by the spread of commercial agriculture, the production of crops for sale rather than for family consumption. Commercial agriculture grew partly because of the recurring need of the peasants for money to meet the mounting demands made on

them by the government and the landlords. Another reason was the fact that such a development was welcome to the British authorities. By the middle of the 19th century, Britain had passed through the Industrial Revolution. British industries were then the greatest in the world, and they kept on expanding. British manufacturers clamored for raw materials and sought good markets in which to dispose of their finished products. Under pressure from British merchants and manufacturers, India's coastal towns were linked with Britain in the 1840's by steamships, and the interior of India was covered after the 1850's by the most elaborate railway network in Asia.

Once the railways were opened, it became possible for the inland areas to produce for the world market. Wheat poured out of the Punjab, cotton out of Bombay, and jute out of Bengal. As commercial agriculture spread, the older practices associated with a self-subsisting economy declined. Since industrial crops (for example, cotton, peanuts, sugarcane, and tobacco) paid better than food grains, the peasants who could tended to shift over to them. In some districts the peasants shifted over completely to industrial crops and had to buy their foodstuffs from dealers. Villagers sent to market the cereal reserves traditionally kept for poor years. They became less prepared to meet poor harvests. Years of successive drought in the 1870's and 1890's led to great famines and agrarian unrest.

To produce crops for market the peasants required credit, and they turned to the moneylender, who came to occupy a place of unprecedented importance. Although in pre-British times the local moneylender extended casual credit to meet occasional needs, he occupied a subordinate place in the economy of the countryside. The new conditions, however, opened up a golden age for the moneylender. The demand for his services became an inescapable part of the peasant's life; to the government the moneylender was of invaluable aid in converting the peasant's crops into cash and passing on the land revenue. He was encouraged to expand his activities by the fact that he could now make a good and secure profit. If the peasants defaulted, he could use the new legal procedure to attach their lands, livestock, and personal possessions. Furthermore, from the middle of the 19th century the price of land rose rapidly, thereby encouraging the moneylender to broaden his operations. He began to take over the peasants' land and rent it out. The moneylenders grew in number and in wealth.

The same railroads which carried away the commercial crops brought back machine-made industrial products. The village artisans no longer were sheltered by the friendly backwardness of the older village commune, and the union of agriculture and hand industry which had been the basis of village life was disrupted. Under the impact of new forces the village could no longer remain a compact social and economic unit. The growing tendency was for each family to make ends meet as best it could. Deep in the interior of central India and in other areas difficult of access the handicrafts held on for a long time, but in the coastal zones and in the regions lying along the new railroads they declined. The village potter, tanner, dyer, oilman, and jeweler all faced strong competition from machine products.

Since 1850 a dwindling proportion of the village artisans have been able to subsist on what they have received for their services from the vil-

lage. Millions of them have had to find other ways to gain a livelihood or to supplement their scanty earnings from the village. In most cases the only avenue open to them has been agriculture, and they have added steadily to the great pressure on the land.

The increase in the number of persons on the land did not reflect itself in an increase in production. Rather a number of related factors endemic in the rural situation served to hold agricultural output down. The hierarchy of rights in the land which was elaborated during the British period established more securely than ever before in Indian history the power of landholders to take a substantial share of the produce of the soil. Persons who enjoyed such rights tended to become set apart from those who actually tilled. Where owners and superior tenants subsisted primarily on rents, the portion remaining to inferior tenants and crop sharers was so small as to keep them stripped of capital; where hired laborers were employed, they were drawn typically from the lowest castes or tribes. Timorous, uneducated, ill paid, and with no stake in any increase in output, these laborers could hardly have been expected to take an interest in advanced techniques or even to make proper use of better tools. Crop production methods essentially remained the time-honored ones passed on from generation to generation.

Associated agrarian problems, such as insecurity of tenure, fragmentation of holdings, and concentration of credit and marketing in the hands of moneylenders, retarded productive investment in agriculture. Families with superior rights to sizable areas found it more remunerative to allow their holdings to be cultivated by others. Rather than plow back profits into the soil in order to obtain higher returns, they preferred to skim off as much rent as could be extracted on the basis of customary methods of production.

A formidable block against modernization was thus provided by a complex of factors which may be summed up in the expression "built-in depressor." Its effects may be seen in the fact that from 1890 to 1947 agricultural output rose so slowly that we are justified in speaking of stagnation. Whatever increases occurred in output took place in industrial crops; there are reasons for believing that to a significant extent these increases were achieved at the expense of food grains.

Urban Economy.—India's urban life in the British period was shaped increasingly to meet the requirements of the economy of the United Kingdom. The chief cities served as centers for the outward movement of British manufactured goods. The factories which came into existence in these cities either were devoted to consumer goods and other light industries or were workshops for maintaining transportation services.

Indigenous enterprise made slow headway in 19th century India, partly because it came up against the power of the British mercantile houses. These houses had evolved a form of business enterprise peculiar to India: the managing agency. Under this managing agency system a single organization runs the affairs of a dozen or more concerns operating in different fields. The system arose when British merchant houses founded banks, opened coal mines, built jute factories, or started tea plantations. After 1850 the great British concerns played a predominant role in the economic life of India. Indians desiring to enter fields in which British managing agencies

operated found it sound or advisable to place themselves under the protection of one or another of these houses. Throughout the 19th century would-be Indian captains of industry received little if any government assistance. The first tariffs of even a moderately protective nature did not come into operation until the 1920's, and up to 1947 the great British shipping lines were able to operate freely in the Indian coastwise trade.

For India as a whole, the great bulk of the town dwellers are not factory workers but hand artisans, unskilled laborers, or servants. Large numbers of laborers are employed in construction and roadbuilding and on docks and railways. The middle classes in the cities consist largely of petty traders, shopkeepers, middlemen, sweatshop owners, and small absentee landlords. From their families come lawyers, schoolteachers, and the lower ranks of government employees. For the middle classes generally the struggle to make ends meet is a hard one, and only a small percentage achieves moderate comfort. In this more fortunate group fall the larger merchants and the successful lawyers, whose main practice is taken up with corporation law and suits about land.

Leaving aside the great British houses, economic power and influence in the cities became concentrated in the hands of a few thousand Indians who successfully established themselves as industrialists and financiers. It was only by 1939 that the Indian houses could be considered to have arrived. Since then all the established firms, British and Indian, have tended to work together to prevent outsiders from intruding into their domain.

Most of the leading Indian businessmen came from two tiny social groups: the Parsis of Bombay and the Marwaris of Rajputana. The most famous Parsi family is the Tatas. Relying almost solely on his own resources, Sir Jamsetji Tata (1839-1904) succeeded in founding at Jamshedpur in eastern Bihar the great Tata Iron and Steel Company. Besides textiles, iron, and steel, his descendants have large holdings in such basic industries as electric utilities, chemicals, machine tools, and trucks. The Marwaris originally were a group of moneylenders and merchants from northern Rajputana. Quick to take advantage of the new economic opportunities presented in the second half of the 19th century, they moved south to Ahmadabad and Bombay and east to Kanpur and Calcutta. Along with the Parsis, they were among the first to set up cotton textile mills. From these they expanded into every conceivable type of business. The wealthiest of the Marwari houses, that of Birla Brothers, Ltd., has interests in cotton textiles, sugar mills, paper companies, cement plants, jute mills, automobiles, trucks, insurance companies, newspapers, and weekly magazines.

Labor.—Factory employment in India at the end of the British period totaled about 2,000,000 workers. In addition, there were about 400,000 miners, more than half in the coalfields; and about 700,000 persons working on the railways. The great cities constituted the chief points of concentration for industrial labor. There were more than 100 jute mills in Calcutta, employing about 300,000 workers; about 100 cotton mills in Bombay with 150,000 hands; and another 100 cotton mills with 100,000 hands in Ahmadabad. Heavy industry was chiefly in the Calcutta-Asansol (coalfields)-Jamshedpur (steel) area, light industry was the specialty of Bombay, and Ahmadabad

was exclusively a cotton mill town.

The principal employers of factory labor were the British and Indian managing agency houses. Insofar as labor supply, wages, and industrial relations were concerned, these houses were in a fortunate position, at least from 1850 down to World War II. Throughout that period India's villages were raising a labor supply larger than that needed in the countryside, and the urban mill-owners could always count on new hands. These rustic recruits were generally from the lower castes, ill educated, timid, speaking different languages, and difficult to organize. Employers found that such laborers would accept the barest subsistence wages.

There was no need, the employers also found, to worry about the laborers' health, housing, sanitation, education, or recreation. The price of such neglect was an unstable and unhealthy labor force. A great many workers had come to the factories because they could not make a living in agriculture. Under the prevailing conditions they found they could not make do in the cities. Many workmen wandered back and forth between village and town. The annual rate of turnover in the mills reached 50 or even 75 per cent.

Down to World War II, India's labor leaders did not emerge from the ranks of labor; instead, they came from the subcontinent's uppermost strata or even from abroad. These leaders usually had political affiliations and carried their political quarrels along with them. While the British were still in power, the imperial authorities distrusted both the trade unions and the political organizations with which these were connected. Laws and ordinances made it difficult for the unions to function.

INDEPENDENT INDIA

When the Indian National Congress took office in independent India in 1947, it had already defined its major objectives for agriculture, industry and trade, and labor. For the countryside the first problem was to raise the standard of living of the masses. Agriculture was to be modernized, and the agrarian structure radically reformed.

The Congress simultaneously called for a rapid development of industry and public utilities "so that free India may develop into a cooperative commonwealth." It would be necessary "to prevent the concentration of wealth and power in the hands of individuals and groups, [and] to prevent vested interests inimical to society from growing. . . ." Therefore the Congress declared: "The State must . . . own or control key and basic industries and services, mineral resources, railways, waterways, shipping and other means of public transport." The system of managing agencies should be abolished, and private industry should be so regulated as best to further the broad interests of national industrial development.

For labor the Congress promised minimum wages, a decent standard of living, proper housing, better working conditions, and social insurance. While accepting the right of workers to form unions, the Congress avoided any reference to the right of those unions to strike. Instead, it promised to establish suitable machinery for the handling of industrial disputes.

Rural Development.—In the first three years of Congress rule at the center and in the states shortage of funds was frequently put forward as a reason for going slow on land reform, since the Congress program called for equitable compensa-

tion of landlords whose rights in land were extinguished. Beyond doubt, India faced many heavy expenses: millions of refugees from Pakistan needed help, the costs of the conflict over Kashmir were huge, and uncertainty about relations with Pakistan led to the allocation of half of the ordinary budget to the military. The question of compensation was eventually resolved by scaling down proposed payments, putting compensation in the form of long-term bonds, and passing (1955) a constitutional amendment making the question of such compensation not open to review by the courts.

Another reason for delay in initiating land reform was the problem of the adequacy of the food supply. From 1947 to 1952, India had poor harvests, and the government had further to strain its financial resources in order to import food. In these circumstances, opponents of land reform questioned the wisdom of radical changes lest these upset food production.

As finally enacted, the land reform legislation fell into two broad groups. In areas where the zamindari system prevailed, the new laws provided for the abolition of intermediaries; these are the famous zamindari abolition laws of such states as Bihar and Uttar Pradesh. In areas under the

patwari, to falsify the village records. Since the laws permitted landholders to cultivate through the use of hired labor or through special kinds of sharecroppers (*sajhidars* in Uttar Pradesh), many former tenants in Uttar Pradesh ended up either as laborers or as *sajhidars* of former zamindars.

In the ryotwari areas the tenancy laws had two main objectives. The first was to protect tenants against eviction by granting those of long standing permanent rights to the land they had been occupying. The second was to reduce rents by fixing upper limits at about one third or one sixth of the produce as against the widely prevailing equal division of the crop. In order to prevent their tenants from obtaining permanent rights to particular plots of land, the landlords took to moving them around from year to year or even from season to season. Furthermore, the landlords connived at the falsification of village records in order to evict old tenants who would otherwise have had full claims to occupancy rights. There were also many cases in which landlords compelled their tenants to sign documents affirming that they were merely hired farm servants (*naukar*).

In a number of states legislation was proposed or enacted to set a limit on the size of holdings. To forestall such ceilings landlords nominally divided their property among their relations or friends so that each of the newly created holdings fell below the proposed maximum.

While the land reform laws enacted in India in the decade after 1947 constitute the largest body of agrarian legislation passed in so brief a span of years in any country, they have proved to be full of loopholes. In effect, the frustration of land reform has carried along with it the frustration of numerous efforts at agricultural development. The grow-more-food campaigns, Community Development Program, National Extension Service Program, Shramdan (labor-gift) movement, Bhoodan (land-gift) movement, Gramdan (village-gift) movement, "Japanese" method of paddy cultivation, foreign technical assistance missions—none of these have been able to make much headway against the deeply rooted forces of the "depressor." Although the official statistics on agricultural output in the 1950's—shown in Table 1—record an increase in production, it would be premature to speak of a sustained upward trend.

Table 1—AGRICULTURAL OUTPUT, 1950–59

ryotwari system the laws provided further protection for tenants; the best known of these is the Bombay act of 1948, which was drastically amended in the 1950's.

While the zamindari abolition laws ended the zamindari system, they did not end the connection of all the former zamindars with the land. The zamindars were allowed to retain lands they could prove to have had under their personal cultivation—their home farms. In Uttar Pradesh such lands were known as the zamindars' *sir* and *khudkasht*. The years of delay before the reforms came into effect gave the Uttar Pradesh zamindars time in which to enlarge their home farms. Wherever they could, the zamindars cleared off tenants and resumed land for themselves. They also induced the village record keepers, the patwaris (Hindi

Perhaps the most fundamental change in the countryside has been the virtual disappearance of *begar* (Hindi *begār*) and other forms of forced labor. In the early years of the 20th century the great bulk of agricultural laborers in India could at best be called half free. In status and practice they are now almost fully free, though still subject to bargaining disadvantages of poverty.

Industry.—In the first dozen or so years after 1947 modern industry grew with unprecedented rapidity and expanded into many new fields. It is not much of an exaggeration to say that in this short period the country made greater industrial progress than in the entire century before independence. Behind this upsurge lay the government's determination to put an end to India's dependence on foreign manufactured products. (Production figures of certain important industrial products are shown in Table 2.)

Table 2—INDUSTRIAL PRODUCTION,

In this development, however, the place of private enterprise, foreign enterprise, and managing agency houses was much greater than the Congress had envisaged. When the party took office, India's business interests made it plain that they were opposed to any program of nationalization or comprehensive planning. They insisted that business be allowed a free hand in its choice of economic activity and be backed up by liberal government assistance. Meanwhile, they decreased their purchases of government bonds and withheld tax payments. Rather than expanding, they cut down on investment programs. In the face of this "capital strike," the government announced in 1948 that nationalization was to be postponed for at least 10 years, perhaps indefinitely. The only industries set aside exclusively for public operation would be munitions, atomic energy, and railways. The government reserved the right to operate in any other field or to establish any regulations it deemed necessary, but stated that private enterprise "has a valuable role to play." In the following year, the government added that foreign capital was welcome and could operate on the same terms as Indian, subject to one basic qualification: major ownership and control should be in Indian hands. By yielding to private Indian and foreign companies the initiative in selecting lines of industry and deciding on intensity of investment in these particular lines, the government in effect was giving up the policy of centrally planned economic development.

In addition to munitions, atomic energy, and railways, the government maintained and ex-

panded its operations in other fields in which it had been active even before 1947: communications, transportation, and electric power, especially hydroelectric installations. In these fields the striking innovation was the manufacture of basic equipment of many kinds, for example, machine tools and railway boilers and locomotives.

The second group of industries in which the government has taken an active role comprises lines requiring capital investment on the order of \$50 million to \$300 million. These industries include complete new iron and steel plants; a shipyard for turning out ocean-going vessels; and plants producing fertilizers, penicillin, and insecticides. Important assistance has been obtained from abroad. In some cases the aid came from foreign private enterprise; in others, as in the steel plant from the USSR erected at Bhilai in Madhya Pradesh, help was given on a government-to-government basis.

For its part, private business has also made big strides forward. There has been great expansion of such established industries as those

Bhakra Dam, a great hydroelectric and irrigation project on the Sutlej River in northern India.

producing iron and steel, paper, small pumps, rubber tires, cement, soaps, and hydrogenated oils. New fields include the manufacture of bicycles, automobiles, buses, and trucks; diesel engines, large pumps, electric motors, and construction equipment; plastics, aluminum, and aluminum products; industrial boilers and air conditioners; rayon, textile dyes, and textile machinery; and fine chemicals, drugs, antibiotics, and other pharmaceuticals.

In this industrial expansion the biggest Indian agency houses were the most active. In the process they secured a still larger lead over their lesser rivals. Hand in hand with India's

unprecedented industrial growth went a greater and greater concentration of economic power in a few firms.

Some of the purely foreign companies carrying on business in India also expanded their operations. Thus, the Indian government arranged with three oil companies to build large new refineries in India. The Burmah-Shell and Standard-Vacuum companies did so in Bombay, while the California-Texas Oil Company did so at Visakhapatnam. In its dealings with foreign companies the government pressed for a steadily rising percentage of Indians in the higher executive posts. A related policy called on the companies to alter arrangements whereby their offices in India merely carried out orders from headquarters abroad. Instead, they were pressed to establish companies domiciled in India, with Indians on the boards of directors, and local shares sold to Indians.

Transportation and Communications.—

As of 1959, the railway system of India extended for some 35,000 route miles. The system is the largest in Asia and, in terms of length, ranks among the first 10 in the world. Barring insignificant exceptions, all the lines are publicly operated, under the Railway Board of the central government. India's highway network (1959) is of the order of 300,000 miles, of which a third is hard surfaced. All the main cities and towns are linked by the government-owned national telephone system. Similarly, the radio network is purely public, under the Ministry of Information and Broadcasting. Domestic air services, nationalized in the 1950's, are handled by the government-controlled Indian Airlines Corporation. The only Indian line providing external connections is the government-controlled Air-India International. There are also a number of foreign airlines serving India, but no one of these runs so many flights as Air-India.

Labor.—During World War II the Communists made great strides in the trade union

movement. To remedy this situation the Congress Party and the government organized in 1947 a new body, the Indian National Trade Union Congress (INTUC), which within a decade became the premier trade union federation in the country. The Communists had the second largest group, perhaps half the size of INTUC or even less; in addition, there were two sets of Socialist-oriented unions and various smaller bodies.

With help from INTUC the Congress has been fairly successful in its announced aim of establishing an industrial truce which would give the most favorable setting for accelerated economic development. To avoid strikes the government has established a compulsory procedure of conciliation and adjudication, with a hierarchy of labor tribunals. The main bias of these tribunals has been in favor of a scaling upward of industrial wages. The fact that the truce has brought more take-home pay accounts in large part for the support given to it by organized labor. Employers have naturally protested, particularly at the slowness of the tribunals. In view of the substantial profits which industry has been enjoying since 1947, however, they seem to have decided that such inconveniences are less troublesome than strikes.

The total industrial labor force has expanded rapidly, reaching about 2,750,000 by 1959. In a number of cases private companies and government corporations have gone to much trouble to provide good working conditions, proper housing, and other amenities. In most industrial establishments, however, conditions are bad. The labor legislation in the statute books is comprehensive, but serious implementation has scarcely begun.

Economic Planning.—India has had a First Five-Year Plan (1951–1956) and a Second Five-Year Plan (1956–1961), and a third plan was scheduled for 1961–1966. An increasing amount of time and labor has gone into the preparation of these documents, but it is no easy task to specify

the achievements of planning. Essentially, planning in India has meant the programming of capital expenditures by the central and state governments. The First Five-Year Plan was drawn up very cautiously; it provided for governmental expenditure on planned items (a good few of which represented projects under way before the launching of the plan) of the order of 20 billion rupees (the Indian rupee is valued at 21 cents in United States currency). The main lines of the Second Five-Year Plan were sketched in 1954 and 1955, when harvests were unusually good. The planners more than doubled the target for governmental outlay on planned items, which was placed at 48 billion rupees. Simultaneously, they called on nongovernmental bodies and individuals to invest in their own activities an additional 24 billion rupees. One of the most striking aspects of the second plan was its vagueness about sources of finance. Dependable resources were expected to provide only 24 billion rupees of the governmental outlay. The remaining 24 billion rupees were to be provided by deficit financing plus hoped-for foreign loans. As to the sources of finance for the private sector, the ideas of the planners were even less precise.

In the first few years of the second plan the planners found that they had seriously underestimated the capital required to reach their production targets, and that they had greatly overestimated their domestic financial resources. Simultaneously, they found that private business had ordered capital goods from abroad at a much more rapid rate than had been anticipated. Moreover, food harvests for the years 1956-1958 leveled off; heavy imports were made. Foreign exchange resources ran dry just when it was plain that inadequate resources were being raised at home. The planners themselves realized the seriousness of the situation, but were unable to devise effective measures for dealing with it. Meanwhile, the first drafts of the Third Five-Year Plan were being outlined. These drafts called for a plan perhaps 50 per cent larger than the second plan. Despite the difficulties already encountered, it seemed to be assumed that basically the same sort of planning somehow could be made to work.

5. WAY OF LIVING

Indian society is composed of many separate fragments which reflect almost every conceivable basis of social differentiation, and which coexist through mutual tolerance and general agreement on the status and functions of the various groups. The geographic regions where different languages are spoken vary considerably in their historical traditions, cultural patterns, and complement of castes. Within each linguistic region marked contrasts in custom and tradition parallel class and caste differences. Cutting across linguistic and class divisions are the communities—large aggregates of people defined by some common denominator, such as religion, ethnic affiliation, or area of origin. Since Indians feel no need to make these diverse groups conform to a single set of

Kulwant Roy

An open-air class at a school in northern India.

practices and beliefs, a bewildering heterogeneity prevails. The underlying unity of the country is derived from the large fund of cultural traditions shared by most groups and from the dominance of certain national elites, who set the goals and the ideology for the nation as a whole.

Family.—By far the most important social unit in India is the family. It is the seat of primary loyalties, and its interests are considered superior to those of the individual. Kinship, which extends as far as ingenuity can trace the bloodline, carries with it an elaborate set of duties, rights, and obligations. The effective unit is the joint family, which usually comprises two, three, or even four generations in a patriarchal, patrilineal, and patrilocal system. This means that the oldest living male progenitor is the head of the family, descent is reckoned through the sons, and brides are brought into the family to live (a daughter, upon marriage, moves to her husband's house). While matrilineal systems still survive, particularly among the Nairs (Nayars) of the southwest coast and the Khasi tribes of Assam, and evidences of earlier matriarchal traits are found scattered throughout the country, the overwhelming majority of Indian families are male centered. New families are created when established units break up upon the death of the patriarch or upon the departure of one or more brothers and their families. The new units acknowledge a common source, however, and maintain a seat (usually where some family land is held) and have household gods peculiar to the family and to its place of origin. In the pure type of joint family property and income are shared among all the members, but increasing mobility and urbanization have produced a freer system in which members merely share responsibility for the support of nonworking dependents. The strictly conjugal family of husband, wife, and children is commoner in the cities than in the rural areas, but it is still not the dominant pattern. Although marriage is almost universal (less than 5 per cent of those of marriageable age remain unmarried), the large cities house many men separated from their families, which have remained in the villages.

Within the family roles are sharply differentiated by age and sex. Until his final declining years a man's status increases as he gets older and, in general, depends upon his standing with respect to the main line of inheritance and upon his contribution to the economic well-being of the family. The role and status of women are more complex. In childhood a girl plays freely with others of her age group, although she early assumes responsibility for the care of children younger than herself. As puberty approaches, however, she is drawn into the exclusive company of older women and is trained for marriage. At or near puberty she is likely to be married and to move to her husband's household, where she assumes the position of an apprentice under the supervision of the women of her new home. In upper-caste groups a dowry system is the commonest, while the bride price is found among other groups. Except among the most cosmopolitan urban elite groups, marriages are still arranged by the parents, with or without the prior consent of the intended bride and groom. A woman achieves full adult status when she gives birth to her first child, preferably a son. From then on her status reflects that of her husband and her sons. Should she become a widow, her status is greatly lowered. Divorce and the remarriage of widows are forbidden in most upper-caste Hindu groups, but they are common among non-Hindu groups and the lower strata of Hindu society. While woman's traditional role requires her to be a passive follower of her husband's wishes, as in all cultures this is subject to constant negotiation. The status of women is improved by the Hindu Succession Act of 1956, which gives them enhanced rights of inheritance in family property.

Within the general framework of the extended family details of such matters as kinship structure, marriage customs, family rituals, and the selection of a marital partner vary tremendously. All groups specify some kinship limits within which a person may not marry (exogamy) and others within which he must marry (endogamy). For upper-caste Hindu groups exogamous boundaries are usually established by some form of the Brahmanic gotra system, which prohibits intermarriage among persons who trace their descent from a common spiritual ancestor. There is also an incest taboo called *sapinda* (Sanskrit *sapinda*), which in its extreme form precludes intermarriage between persons whose relationship is within six degrees on the father's side and four degrees on the mother's side. In the south, to the contrary, the preferred mate is the cross-cousin (for a man, the daughter of his maternal uncle). Endogamous boundaries are usually the caste or the subcaste.

Caste.—Among the Hindus and Jains, and to a lesser extent among the other religious divisions, a group of families forms a caste which may vary in size from a few hundred to several million. Membership in a caste is by birth and is unalterable. An individual's choice of a marriage partner is generally restricted to his own caste, and even in cities intercaste marriages are rare. The castes are arranged hierarchically according to the prestige of their traditional occupation and the extent to which they observe such social practices as special food taboos, strict vegetarianism, and the prohibition of widow remarriage, according to traditions prescribed in Sanskrit literature.

The caste system is intermingled inextricably

with Hinduism, deriving part of its strength from a religious philosophy which justifies a person's present position by his deeds (*karma*) in previous existences and promises a better status in his next existence if he fulfills his duty (*dharma*) by conforming to the rules of his caste today. While caste is thus sanctified by religion, it has many social pressures to support it. Other religious groups, such as the Sikhs, Muslims, and Christians, while doctrinally opposed to caste, have nevertheless formed castelike groups, which frequently reflect their affiliation prior to conversion from Hinduism. Social distance between the castes is symbolized and maintained by taboos on intermarriage and on eating together and by the restriction of access to temples, wells, schools, and other public places. Where the difference in status is very great, physical contact is prohibited.

The relative position of the caste varies from one locality to another, and no single locality contains the complete range of more than 2,000 distinct units called castes. In general, however, the castes are fitted into the broad class divisions of the four *varnas* (Sanskrit *varna*) mentioned in the Vedas and systematized and stabilized in later Brahmanical literature. The Brahmins (*Brahmana*, priests), Kshatriyas (*Kṣatriya*, warriors and rulers), and Vaisyas (*Vaiśyas*; Sanskrit *Vaiśya*, commons) comprise the three upper groups. Men of these groups wear the sacred thread and are called twice born (*dvija*), because as boys they undergo a ritual initiation ceremony (*upanayana*). Sudras (*Shudras*; Sanskrit *Śūdra*, serfs), the fourth *varna*, rank below this group. Outside the *varna* system entirely are the castes labeled untouchables, *Harijan*, or scheduled castes, as well as various tribal groups which have not been assimilated to Hindu society. The Indian Constitution forbids the enforcement of the disabilities arising out of untouchability, and the Untouchability (Offences) Act of 1955 provides legal penalties for its practice. Both the central and the state governments have done much to raise the social and economic level of these classes.

An individual may raise his own esteem and influence and that of his family by the acquisition of wealth (especially land), education, political power, and special religious merit, and over the generations whole castes often attempt to rise in the hierarchy. Individuals are not restricted to traditional occupations, although some occupations are monopolized by one or a very few castes, and all castes can and do engage in agriculture. With greater vocational opportunities the concordance between caste and occupation is decreasing in modern India. In the cities education has become a much more important determinant of occupation, although the different castes are still unequal in their educational attainments.

Village Life.—It is in the villages, where more than four fifths of India's people live, that caste appears in its fullest development, providing a stable division of labor and a well-defined system of rights and duties. The completely self-sufficient village or cluster of villages is now found only in isolated areas. The motor bus, the radio, the centralized market, and the proliferation of governmental functions and functionaries have made the villages dependent on the outside world. Nevertheless, the predominant village structure, though weakened, is much the same as it has been for centuries.

Except for a few specialized villages such as those of fishermen or herdsmen, the cornerstone of

village life is the land and the agricultural cycle. About 70 per cent of the people of India depend on agriculture for their livelihood. The leading agriculturists in the villages (48 per cent of the total population) either own the land or have superior tenancy rights. Below them are the lesser tenants (9 per cent) and a growing class of landless agricultural laborers (13 per cent). The uneven distribution of the land has produced an aristocracy: 25 per cent of the village families hold 84 per cent of the land. In most areas the majority of holdings consist of less than five acres. Land is usually held by a joint family, and upon a division of the family each child receives a share. Increasing population density and generations of subdivision have reduced many holdings to an uneconomic size and scattered them in unconsolidated fragments.

Aside from agriculturists, each village usually has a set of separate castes which provide it with artisans and servants. This segment varies from village to village, but most commonly it includes one or more families with the occupations of blacksmith, carpenter, barber, potter, oil presser, washerman, sweeper, cobbler, and scavenger, and perhaps also a weaver, a temple servant, and a moneylender-shopkeeper. In earlier times some or all of the artisans and servants were paid from shares of the harvest, and they were attached in traditional patron-client relationships (called *ya-jamāni* in north India) to the agricultural families and to each other. These networks of mutual obligations have been undermined by the growing tendency to deal in cash rather than in kind, by the temptations of urban employment, and by the development of an external source of supply for many services previously provided within the village itself.

Most Indian villages are nucleated—that is, they fall in a cluster of 50 to 500 houses strung along a few narrow lanes and surrounded by their fields. At the 1951 census, 26.5 per cent of the rural population lived in villages with fewer than 500 persons; 48.8 per cent, in villages housing between 500 and 2,000 persons; 19.4 per cent, in villages of between 2,000 and 5,000; and 5.3 per cent, in villages of over 5,000. Truly dispersed households are found only in the Himalayan area, but in Bengal there are clusters of single family homesteads; in the Punjab there are dispersed hamlets; and linear strip villages are not uncommon along the main rivers and along the roads in Kerala. Each village usually has four or five clearly demarcated social areas, including one outside the central cluster for the lowest caste. Even the humblest house is likely to have a walled-in open space where most of the family living takes place. But no matter what the geography of a specific village, poverty, petty tyranny, and repetitiveness are the common pattern. As a respite from the unending routine, the religious festivals, the happy rites of passage, and the frequent weddings take on a special significance. They also drain a disproportionate share of the villagers' scant cash income and sometimes add to an already staggering inherited family debt.

In 1952 the Indian government launched a massive Community Development Program to transform the economic and social life in the villages in the hope of arresting the downward spiral of agricultural life. Together with the less intensive National Extension Service Program, it had reached 80 million persons and about one fourth of the villages by the end of the First Five-Year

Kulwant Roy

Acharya Vinoba Bhave (left), leader of India's land-for-the-landless movement, maps a local campaign.

Plan (1951-1956) and was scheduled to cover the entire country by the end of the Second Five-Year Plan (1956-1961). The program's goals included increases of 28 per cent in agricultural production and 17 per cent in agricultural income, the provision of 2 million additional jobs in the rural areas, and the establishment of a road, a post office, and a telegraphic office within five miles of each village. The unit of operation is the Development Block, which contains an average of 100 villages with an aggregate population of 60,000 to 70,000 persons and an area of 150 to 170 square miles. Funds are supplied mostly by the central government, but the projects are administered and executed within the states.

The program has a staff of 100,000, but the key position is the lowest, that of the worker who is in charge of seven villages and actually instigates the changes. His task is essentially one of persuading the villagers to accept such innovations as improved plows, seeds, and planting techniques, which are disseminated by the technical departments of the government, and to mobilize them to build such community facilities as roads, irrigation ditches, wells, sanitary facilities, and schools, which they can produce with only a little outside capital. He is also responsible for promoting various changes in social organization which the government considers essential, including the development of cooperatives and village panchayats (councils), the consolidation of holdings, the encouragement of handicrafts and small industries, the organization of programs designed to assist the weaker elements of the village community, and the improvement of the lot of the scheduled castes and tribal groups. It is small wonder that, when successful, the program is called a rural revolution. Assisted by favorable climatic conditions and initial enthusiasms, the results were generally impressive during the First Five-Year Plan, although some sections of the country lagged behind the rest. Subsequent estimates were less sanguine; visualized a longer, harder pull; and suggested the need to concen-

Balder from Rapho Gullumette

Roadside restaurant in Chandigarh, capital of the Punjab. In the background is the capital's Secretariat building.

trate efforts on the key problems of agricultural improvement, postponing welfare provisions to a later date.

One of the major criticisms of rural development is that the benefits from the program have by and large gone to those elements in the village which are already economically well off. A non-official program of national importance, aimed in part at correcting this tendency, is the Bhoodan (land-gift) movement, begun in 1951 by Acharya Vinoba Bhave, a disciple of Mohandas K. Gandhi. Bhave and his followers travel from village to village requesting donations of land to be redistributed to the landless agricultural laborers and poorer tenants in the villages. By 1958 about 4.4 million acres had been donated, and of this approximately 1 million acres had been redistributed. More orthodox procedures for land reform are various land tenancy acts passed by state governments. Under these acts land is acquired by the state, ceilings are established on holdings, absentee owners and rent-collecting intermediaries are outlawed, and a minimum size is set for holdings in order to prevent further fragmentation. Evidence of the success of such legislation is conflicting.

City Life.—India's urban areas grow at a very rapid pace, and the large cities grow the fastest of all. While only a little less than one fifth of the population was classified as urban at the 1951 census, each of the 10 largest cities more than doubled its population between 1931 and 1951, by which time there were 32 cities of more than 200,000 inhabitants. This growth was given further impetus by the immigration of some 8 million Hindu and Sikh refugees from Pakistan to the major metropolises of northern and western India. The marked growth of cities is also a result of increasing economic pressure in the rural areas (more than one third of the city dwellers of the 1950's had migrated from villages), but there has been no compensating expansion of the economic base. The number of workers in organized manufacturing industries has remained relatively con-

stant, aggregating only 2.5 million in 1951, and most city dwellers are employed in service and distributive occupations which add little to the national income. The results can be seen in the deepening poverty of the cities, in the proliferation of rural housing types in uncongenial urban slum settings, and in the overflow of the population into the streets in search of living quarters.

The urban housing shortage, already acute, worsened in the 1950's, and congested areas in industrial cities reached densities of 700 or more persons per acre. House styles tended to be of a rural type without the saving grace of open air and sunlight found in the villages. In 1953-1954 a national sample survey was made of conditions in 53 towns and in the cities of Bombay, Calcutta, Delhi, and Madras. It found that nearly one fourth of the houses had plinths, walls, and roofs of mud. About 44 per cent of the houses had one room; 28 per cent, two rooms; 12 per cent, three rooms; and only 16 per cent, four or more rooms. About 46 per cent of the houses had less than 100 square feet per head. These figures do not tell the full story of the urban slum building itself, called *bustee* (Hindi *basti*) in Calcutta, *ahata* in Kanpur, *cheri* (Tamil *cēri*) in Madras, and *chawl* (Hindi *cāl*) in Bombay. Perhaps the most livable is the *chawl*, which is usually a three- to six-story building with approximately 20 one-room units to a floor, each about 120 square feet with an additional kitchen of 60 square feet. At one end of the floor is a common latrine and bath. The rent of 50 rupees per month for each unit is too high for a laborer's income, and two or three families often occupy the same cubicle. The housing shortage and spiraling rents have pushed even middle-class families further and further down in the housing scale. The rows of tenements are separated by narrow lanes that rarely see the light of day, a constantly running water tap serves an entire neighborhood, and open sewage gutters and overflowing trash bins add to the squalor. Problems of slum clearance, including compensation and displacement, are beyond the means of the municipal improvement trusts established in most cities to fight urban blight. Construction in the private sector of the economy tends to concentrate on expensive houses which charge high rents, little capital is available for housing, and cooperative housing has made slight progress. Moreover, since improvements are economically nonproductive, their priority is likely to remain low in governmental development projects.

In the center of each town there is usually a bazaar, a series of parallel strips crowded close together, each segment offering a single line of wares. Stalls ordinarily open at the front, and the shopkeeper sits on the veranda facing the street. Each of the larger cities has a center of shops on Western lines with glass fronts and rows of counters. If the town or city has been an administrative center, it has a cantonment and civil lines where the military, civil service, and European sections of the population resided. These areas contrast starkly with the jumbled, crowded sections elsewhere. In any available spot there are squatters' shacks made of corrugated iron, reed and wattling, mud, or whatever else is handy.

Most cities are sharply divided into sections, relatively homogeneous as to class, ethnic origin, and economic position. The upper stratum is composed of remnants of older elites—absentee landowners, rulers of former princely states and their dependents, religious leaders and scholars,

and wealthy traders and merchants of such special mercantile communities as the Parsis, Jains, Khojas, Marwaris, and Chettisars. The most important urban elite, which either includes or dominates the older wealthy classes, is the middle-class group of professional men, government servants, and intelligentsia, which has absorbed part of the Western cultural heritage in varying proportions and degrees of harmony. Its influence far outweighs its numbers. At the highest estimate this elite includes the 5 million persons literate in English, but several hundred thousand out of a population totaling about 397 million in 1958 is a more realistic estimate. While this group is almost entirely urban, it not only sets the tone of the cities, but also formulates the unifying goals of the country. The unquestioned national leadership of the elite stems from a number of factors, including its service to the nation in the achievement of independence; the general high regard for education and the professions; the national commitment to rapid modernization; and the group's control of the governmental machinery, which affects most aspects of society.

The city has a much greater range of occupations than the rural areas, and an individual must therefore rely upon many more persons to supply his needs. He comes into contact with more and more people but in a more impersonal and specialized relationship. Some of the needs of the city dweller for group membership are met by the development of voluntary groups and associations, but the village and the original rural base of the family draws the temporary urbanite when he is ill, ready to retire, or faced by a major family crisis. The temporary nature of urban residence is reflected in the distorted sex ratio (it is as low as 570 females for every 1,000 males in Calcutta), which is a result of the tendency of men to go to the city for what they consider a short stay, leaving their families in the village to await their return. The stay is rarely short. Nevertheless, urban households are larger than those in rural areas, averaging 6 persons as compared with 5.5. This is an indication of the pressure on housing and of the size of the dependency load which a city dweller assumes once he is established.

Demographic Pattern.—Underlying many of India's problems and running a race with its development is its population growth. India has an estimated crude annual birth rate of 40 per 1,000 persons and a death rate of about 27, providing a natural increase of 1.3 per cent annually. This rate is not excessive. In the 1950's, North America was growing at a rate of 1.7 per cent per annum, Africa at a rate of 2.2 per cent, South America at 2.4 per cent, and the world as a whole at 1.6 per cent. Several factors, however, make India's growth a source of difficulty. In the first place, the base population is so large that the actual number involved in the relatively low rate of growth is over 5 million persons a year. In the second place, pressures on the food supply already require India to expend a considerable portion of its foreign exchange on the importation of food. In the third place, the rate of growth is not the same throughout the country, being heaviest in those areas where the greatest density and pressure on resources already exist. In the fourth place, the necessity of allocating a substantial portion of future economic growth to the additional population hampers attempts to raise the general standard of living. Finally, by

the 1950's India was only at the halfway mark in a process which was expected to increase the rate of growth before a decline in births restored the equilibrium.

As in most 20th century underdeveloped countries and in Western countries in previous centuries, the spurt of population in India was precipitated by a sharp decline in the death rate, produced by relatively rapid and thorough control of such major epidemic diseases as plague, cholera, smallpox, influenza, typhoid fever, and typhus. While these diseases were still prevalent in India in the 1950's, inoculation campaigns had cut their mortality rate to less than 300,000 deaths annually. Malaria, responsible for about 800,000 deaths annually, with perhaps 57 million persons suffering from it, was being controlled by extensive DDT spraying, which was expected to produce a further decline in the death rate. India was also giving high priority to the reduction of infant and child mortality, and between 1950 and 1955 infant mor-

Gordon N. Converse, "The Christian Science Monitor"

A policeman directs traffic in a Calcutta street.

tality decreased from 127.1 to 99.9 per 1,000 live births. Further progress in this field would have a double-edged effect. Not only would it reduce the sizable death rate, but it would enable many more children to survive into the fertile ages and thus would raise the birth rate even further. The only major disease with a high mortality rate which was clearly on the increase was tuberculosis, which accounted for as many as 500,000 deaths a year. An extensive BCG (*Bacillus of Calmette and Guérin*) campaign sponsored by the United Nations Children's Fund and the World Health Organization had resulted in the inoculation of more than 24 million persons, and the Second Five-Year Plan was attempting to reach the entire susceptible population under 25 years of age. Meanwhile, however, partly as a result of urbanization and declining nutritional levels, the disease was increasing rapidly. Other communicable diseases, such as trachoma, filariasis, and venereal diseases, while still high in incidence, did not directly affect the mortality rate.

Although the death rate can be reduced by relatively efficient and easy methods, a reduction in the birth rate is much more difficult. The Indian government is one of the few that have adopted birth control as an element in state policy. While studies have shown that sizable sections of the population are willing to state a readiness to accept family limitation, field experiments have been conflicting in their reports of the actual success of birth-control programs. Initial trials of the rhythm method were not successful, and the central government adopted the more cautious approach of making advice and assistance available when they were sought. In two Indian states, Madras and Mysore, campaigns were started to encourage mass sterilization after the third child, offering free hospital care and a premium of 25 rupees.

While there are no religious barriers to birth control per se, many institutional pressures promote high fertility. There do not seem to be marked differences in fertility between classes, occupational groups, income groups, or urban and rural residents. While there is some evidence pointing to an advance in the age of marriage, this is largely among women under 20 and thus promises no decline in fertility. A major decline in the birth rate probably awaits changes in the factors that encourage high fertility, such as early and universal marriage, the high prestige accorded women upon the birth of sons, the heavy infant mortality, and the religious encouragement of fruitfulness.

The demographic pattern places special burdens on the economy, for the low average age of the population is one factor accounting for the heavy load borne by the economically productive. The high birth and death rates produce a young population: 13.3 per cent of the population was under 5 years of age and 47.5 per cent under 20 years of age at the 1951 census. A boy born in

that year had an average life expectancy of 32.5 years. Only 29.3 per cent of the population was self-supporting and 60.1 per cent was classified as nonearning dependents in 1951. The burden fell largely on agriculture, from which 68.1 per cent of the self-supporting population obtained its livelihood. This dependence on agriculture has made population density vitally important. The high density regions are the Gangetic Plain in the north (832 persons per square mile in 1951) and the coastal strips on either side of the southern peninsula. The Deccan and the western thrust of Gujarat and Kathiawar are of medium density, and the mountain fringes and the desert of Rajasthan (61 persons per square mile) are of low density.

Dress.—The commonest garment for Indian men is the dhoti (Hindi *dhoti*), a four- to five-yard white cotton cloth wrapped around the waist and tucked between the legs. There are variations in its drape, length, texture, and quality of border adornment. In Bengal one end hangs loose in front, while in Maharashtra both ends are passed between the legs and tucked into the back waistband. The poorer peasant or laborer wears his dhoti very short, and it is made of low quality cloth; that of the well-to-do man hangs in full folds from the waist and is made of fine muslin with a border edged in silver or gold thread. Working-class Muslims and some non-Muslim peasants wear a lungi (Hindi *lungi*), a two-yard piece of cloth, frequently checkered, which hangs loose and is wrapped around the waist like a sarong. In the Punjab loose-fitting pajamas called shalwar (Persian *shalwār*) are worn. If a shirt is worn, it is long and hangs outside the lower garments. In the cities and among the cosmopolitan groups in the towns and rural areas, Western dress is common for men. A three-quarter-length coat called achkan, buttoned all the way up the front and topped with a short, stiff collar, is worn as the official Indian costume on formal occasions.

Most Indian women wear the sari (Hindi *sārī*), a bordered length of cloth from six to nine yards long, which is draped loosely around the entire body and frequently covers the head as well. Except in lower-class groups, where it may be the sole garment, it is normally worn over a half slip. The sari is wrapped around the waist several times, making pleats in front, and then thrown across the chest and shoulders. Either a full blouse or a short, halterlike garment called a choli (Hindi *choli*) is worn on the upper body. The quality of the sari ranges from the drab blue or white of the peasant's workaday sari to the heavy gold brocade or fine gold-threaded silk sari of the rich. A few Indian women, particularly among such highly Westernized communities as the Parsis, Christians, and Anglo-Indians, wear dresses. In the Punjab women wear the shalwar topped by a long shirt, and in scattered places in north India a full, flowing skirt is worn.

Footwear for both men and women consists usually of sandals. For men distinctive styles of headdress indicate regional affiliation, religious community, or social class. Aside from the many ways of wrapping the turban, special headwear includes the traditional Parsi hat of shiny starched black alpaca in the shape of a rimless bowler; the Muslim hat, preferably of angora wool; and the Gandhi cap, an unadorned visorless cap which originally denoted membership in the Congress

Veiled Muslim women enter the polling place to vote in India's general elections.

Kulwant Roy

Party. Women usually wear no headdress other than a shawl or the end of the sari.

Food.—Most caste Hindus are vegetarians, varying in the strictness with which they observe the religious prohibition against meat. For Muslims, Parsis, and Christians, fowl, mutton, buffalo, and goat are the commonest meats. These are usually cut into small pieces and served with a curry. In the coastal regions several fine varieties of fish are served. In general, however, the diet is vegetarian, consisting mainly of grains (wheat, rice, millet, and barley) and legumes (grams, beans, and pulses). Wheat, usually served in baked or fried cakes, is the staple in northern and western India. The chapatty (Hindi *capāṭī*), the commonest form of bread, is a round, flat cake made of whole wheat flour and baked on a convex iron plate. The *puri* is like the chapatty except for the addition of some shortening, but it is fried in deep fat; the *parāṭa*, a third kind of bread, is cooked on a convex metal pan. In eastern India and in the south rice is the staple. Usually it is simply boiled, but mixed with ghee (Hindi *ghī*, clarified butter) and spices it becomes pilau. Corn, barley, and the millets are served alone or as supplements to wheat and rice dishes. Primary sources of proteins are the grams and pulses, such as *mung* (a green pulse), *channa* (Hindi *canā*, a chick-pea), and *arhar* (the pigeon pea), which when split and dried are called dal (Hindi *dāl*).

Vegetables include most of the green leafy vegetables, especially spinach and mustard and radish greens, as well as gourds, eggplant, okra, cucumbers, cabbage, turnips, and potatoes. India is well endowed with a large variety of fruits. Mangoes, undoubtedly the most popular, occur in several dozen varieties and are served in many forms. Most of the citrus fruits are cultivated, and guavas, tamarinds, papayas, custard apples, jack fruit, breadfruit, melon, gooseberries, pomeles, and pomegranates also are plentiful. In the hill regions such temperate zone fruits as apples, pears, strawberries, and cherries are grown. Milk products, especially curds, and a great variety of sweets round out the diet.

Most Indians eat a very light breakfast upon arising, a heavy meal at 11 or 12 o'clock in the morning, and a lighter meal between 7 and 9 o'clock in the evening. In the towns and villages tea is consumed throughout the day.

6. EDUCATION

Educational System.—India's educational system is a mixture of a number of different traditions. In earlier days there were in the villages *tols*, schools for training caste Hindus, particularly Brahmans, in the traditional lore and sacred learning; *parishads*, assemblies of learned men for the instruction of the young; and *pāṭhśālās*, more formal primary schools open to all castes except untouchables, and taught usually by village priests. For Muslims schools known as *maktabs* were attached to the mosques, and independently operated madrasahs offered instruction at the secondary level. For the wealthy there was a host of private tutors.

The spread of formal schools under either government aegis or government regulation has made heavy inroads on the traditional system. In the late 1950's about 40 per cent of the children from 6 to 11 years of age and about 29 per cent of those from 12 to 14 years of age were enrolled in formal schools. Of the 366,686 schools recognized by the government in the 1955-1956 school year, about one third were private institutions, in the sense that they were owned and operated by nongovernment groups, particularly religious organizations. Nevertheless, the overwhelming majority of private schools receive governmental subsidies, and all recognized schools must follow syllabuses and their students must pass examinations set by state or local governments. Out of 33,923,000 students enrolled in the school year 1955-1956, approximately 10 million were in private institutions receiving government aid, 1 million in unaided schools, and the rest in schools run either by district or municipal boards or directly by the various states or the central government.

The full educational cycle normally begins with the primary school: there are few preprimary schools in India. Many of the primary schools have only one or two teachers, who instruct all grades from the first to the fourth. Middle schools carry the student from the fifth through the eighth grade, and secondary schools take him through the eleventh grade. Gradually the middle schools are disappearing, their coverage being divided between the primary and the secondary schools. Until India became independent in 1947, the schools were either vernacular or Anglo-vernacular. Schools of the former type were considered to offer a terminal education, while those of the latter type prepared students for college. With the de-emphasizing of English and the growing importance of vernacular instruction, however, these differences are being obliterated.

At the end of his secondary schooling the student takes a general examination, set either by a state board or by a university, which qualifies him as a matriculate. This is usually the lowest educational level to make him eligible for a white-collar job. His standing in the matriculation examination also determines his eligibility for admission to a college or university. Normally he then proceeds to a college, and at the end of two years takes another standardized examination, called the intermediate, and after another two years receives his bachelor of arts or bachelor of science degree. Following this there are various professional schools and postgraduate courses taught at universities.

Higher educational institutions are of several kinds. The bulk of the teaching is done in colleges of arts and sciences, of which there were 712 in 1958; professional colleges, numbering 346; and special education colleges, numbering 112. The 37 universities are divided into three types. The oldest of these is the purely affiliating university (only 5 were left in 1958), which follows the British pattern whereby the university does not itself undertake any teaching but prescribes courses of study, conducts examinations, and awards degrees and diplomas for the colleges affiliated with it. The second type, comprising 20 universities, adds some teaching, usually at the postgraduate or postintermediate level, to its main task as an affiliating body. The third type, represented by 12 universities, is a

UNESCO

residential and teaching unit controlling directly all the colleges as subdivisions. A university may have as many as 136 colleges (Calcutta) or as few as 1 college (Aligarh) attached to it.

Educational Problems.—There are many problems associated with education in India which press for a rapid solution. In the first place, the size of the task, given India's resources, is almost prohibitive. According to the 1951 census, 19.9 per cent of the people over 10 years of age were literate. The proportion varied from 58.3 per cent in Travancore-Cochin (roughly equivalent to the new state of Kerala) to a low of 5.8 per cent in Himachal Pradesh and 8.6 per cent in Rajasthan. Low salaries and the reluctance of educated persons to reside in the villages hampered the recruitment and diffusion of teachers needed to reach the goal of universal compulsory education through the primary level by 1961. A high turnover in the lower grades and frequent lapses into illiteracy have made the task more difficult.

The spread of basic education and its integration with the predominant academic system have not been easy despite strong official backing. The increasing use of vernacular languages has been purchased in part at the expense of the ability of students to use English and a consequent limitation of intellectual access to the West. The decline of English and the emphasis on the vernaculars as media of instruction threaten to destroy the nationwide unity of the educational system. Moreover, the gap in technical and professional education is seriously hindering India's program of rapid economic development. The examinations-centered system, with its almost ritualized curriculums, served originally to standardize an extremely diversified educational structure, but it has led to the practice of rote memorization among students and to a tendency toward inflexibility in the content of instruction. Access to education for women and lower-class groups has been extremely limited, although special governmental scholarships are in part redressing the balance. And as a paradox, in a country where illiteracy is the rule, there is a vast and growing group of high school and college graduates unable to find employment. Indians are aware of these and many other problems in education,

however, and they are working very hard to solve them.

Libraries and Museums.—Public libraries are operated under municipal or state auspices in most of the larger cities, and there are small libraries in many towns and villages. The largest collection is that of the National Library in Calcutta, which had more than 800,000 volumes in 1957. Many government departments maintain excellent libraries, as do the various universities and learned societies. In 1958 the Gandhi Memorial Foundation opened at Madurai the first of a series of Gandhi libraries.

Most of the museums in the country belong to the Museums Association of India, whose headquarters are in Bombay. Among the most important collections of art and archaeology are those in the National Museum of India, New Delhi; the Prince of Wales Museum of Western India, Bombay; the Government Museum and the National Art Gallery, Madras; the Rajputana Museum, Ajmer; the Baroda Museum and Picture Gallery, Baroda; the Archaeological Museum, Mathura; and the Indian Museum, Calcutta.

7. ARCHITECTURE AND ART

Although the main sites of the most ancient art of the Indian subcontinent, that of the Harappa civilization (c. 2500-1700 B.C.), are situated in Pakistan, proto-Indian art was not confined to the Indus Valley but extended as far south as Lothal, near Ahmadabad, and as far east as Rupar, on the upper Sutlej River. The art of the 1st millennium B.C. down to the 3d century has survived only in stupas (Sanskrit *stūpa*), such as that at Kausambi, Uttar Pradesh; abstract copper-sheet figurines (Bisauli, Uttar Pradesh); the 25-mile-long fortifications of Rajgir, Bihar; and rock paintings in Raigarh, Madhya Pradesh.

3D CENTURY B.C.—4TH CENTURY A.D.

The continuous history of Indian art begins with the Maurya dynasty (321?-184 B.C.), whose rulers made Pataliputra (modern Patna) in Magadha, Bihar, the capital of an empire which extended in the northwest into Afghanistan and Persia. Both Pataliputra and the other large towns on the highways which brought Persian forms to India—Taxila, Ayodhya, Vidisa, and Ujjain—were built of perishable materials. Under Asoka (r. about 274-237 B.C.) the original wooden columns of the palace hall at Pataliputra were replaced by stone columns of Achaemenid design. A park laid out like the formal Mughul (Mogul) gardens 2,000 years later surrounded the palace.

Columns and Stupas.—Following the bloody conquest of Kalinga (modern Orissa) about 262 B.C., Asoka was converted to Buddhism. Thereafter, bent on peaceful conquest, he promulgated his principles of righteous government by having them engraved on rocks and columns. The characters of the inscriptions, which are incised with a precise beauty, are the first evidence of an Indian script (Brāhmī) after that of the proto-Indian seals. The monolithic, tapering shafts of the columns are embedded for about one third of their

height and are supported underground by brick platforms. Their equally monolithic capitals, of an inverted lotus shape, are fixed to the shaft by an inner copper bolt. In certain cases, as at Sarnath near Varanasi (Banaras), the capitals supported the wheel of the law, its spokes carved exquisitely in the round. Each column symbolized the cosmic pillar, holding heaven and earth apart, and signified ordered life under a righteous government. The carving of the capitals is related to that of Achaemenid Persia, in whose empire the Punjab had been included from the mid-6th to the late 4th century B.C.

Altogether different and indigenous in style is the elephant, dated in the ninth year of Asoka's reign, whose front half emerges from the vertically planed surface of a rock in Dhauli, Orissa. The animal is carved in basic shapes which suggest elephantine structure and movement, and its outline is assimilated to that of the hill in which its hind part is hidden.

Carving from the living rock is a technique that is also employed in sanctuaries of the Ājivika sect hollowed out of Barabar Hill near Gaya, Bihar. Their small, rectangular halls have highly polished walls and straight or vaulted ceilings. In two instances (Sudāmā and Lomas Rishi caves) a small circular or oval chamber is hollowed out behind the narrow end of the hall.

The *Bauddhāyana Dharmasūtra* (2: 2, 6, 33) says: "It is impossible for one who lives in a town to attain salvation." A turning away from town life, together with a desire for visual evidence of the everlasting truth of their religion, led monks of the reform movements of Jainism and Buddhism to excavate rock-cut temples and monasteries in the hills. The same desire prompted the adoption of stone for stupas and other religious structures.

Legend credits Asoka with having set up 84,000 stupas. Originally a stupa was a mound erected over the relics of a chieftain, earth being heaped around a central pillar. For Buddhists the stupa over the relics of the Buddha or those of his disciples was symbolic of the *parinirvāṇa*, the total decease through which the Buddha left the human body and assumed universal reality. In Asoka's time stupas were made of bricks piled in a solid dome shape, called *anda* (egg), rising over a circular plinth. They symbolized the cosmos under the dispensation of the law (*dharma*) of the Buddha. The stupas piled in Asoka's reign were subsequently enlarged by overmantling and were faced with stone slabs. (Asoka himself had the stupa at Nigliwa, Nepal, enlarged.)

Rock-Cut Temples and Monasteries.—The impact of the official art of the Mauryas, as represented by free-standing stone pillars, was felt as late as the 1st century A.D. (capitals of the South Gateway at Sanchi, Madhya Pradesh), although they are overwhelmed by the wealth of indigenous forms amid which they appear. The monumental art of the period from the 1st century B.C. to the 1st century A.D. was created mainly in the service of Buddhism. In the Western Ghats (Bhaja, Nasik, Kondane, Bedsa, and Ajanta) apsidal rock-cut temples reproduce structural buildings by means of monumental sculpture carved in the natural rock. Representations of contemporary wooden buildings are found in reliefs on the railings and gates of stupas and in paintings on the walls of caves. The buildings range from single-roomed, domed huts to multistoried mansions having open pillared halls on the ground floor, bal-

conies with railings along each of the upper stories, closely spaced arched window or door openings, and wagon-vaulted roofs with dormer windows. Sanctuaries either resembled these mansions or were laid out on a central plan. A special case is the tree temple of Bodhi (Buddh) Gaya, Bihar, whose galleries enclose, and whose dome was surmounted by, the bodhi ("bo") tree under which the Buddha attained enlightenment.

In Bairat, Rajasthan, exist the foundations of a structural, circular brick temple with wooden pillars (c. 3d to 1st century B.C.), which was similar to the pillared and domed circular temple with a vaulted ambulatory (1st century A.D.) cut out of the rock at Junnar, north of Poona in the Western Ghats. Also of the 1st century A.D. are the apsidal temples at Nasik and Bedsa called chaitya (Sanskrit *caitya*) halls, whose plan results from a contraction of the rectangular hall and circular sanctuary. The façade of these chaitya halls is dominated by a large circular window (*gavākṣa*) in the middle of the second story, while the small door opening in the middle of the ground floor is surmounted by a smaller, solid *gavākṣa* shape. In earlier rock-cut temples, such as that at Bhaja (1st century B.C.), the façade was pierced in the middle by a large arched opening closed by a wooden screen. Although this combination of timber construction and stone carving was abandoned, even in one of the last and the most magnificent of this series of rock-cut temples (Karli or Karle; early 2d century A.D.) arched wooden beams were attached to the vault of the apsidal hall. Light from the large *gavākṣa* falls on the rock-cut stupa, the main cult object, at the opposite end of the hall. Thick, closely set pillars divide the narrow aisles from the nave and extend behind the stupa, forming an ambulatory whose darkness makes the walls of the interior (124 by 45 by 45 feet) recede into the distance. The octagonal pillars of Karli, with their vase-shaped bases and faceted, lotiform capitals surmounted by inverted pyramids carrying sculpture groups, are far in advance of the thin, timberlike, sloping posts without base and capital of the earlier temples.

Rock-cut monasteries called viharas (Sanskrit *vihāra*) or *saṅghārāma* were given their perfected form in the 2d century A.D. at Nasik (Caves No. 10 and No. 3), where a pillared veranda leads to a large, square central hall with cells on three of its sides. This arrangement is an adaptation of a structural cloister with a square central court. In the two-storied Rāñi Gumphā Cave (c. 1st century A.D.) on Udayagiri Hill, near Khandgiri, Orissa, however, the cells are ranged on three sides of an open court.

Sculpture.—In the decoration of monuments sculpture served both as an illustration of doctrine and as an evocation of its meaning. Stupas and other sacred objects were surrounded by railings (*vedika*), to which gates (*torana*; Sanskrit *torāṇa*) were added. Stone versions of wooden fences, these railings have thick rectangular posts, crossbars, and coping stones, carved with rectangular, circular, or friezelike relief compositions or with large single figures. The low reliefs in Stupa No. 2 at Sanchi (c. 2d century B.C.) are symbolic configurations mainly of plant (lotus) and animal shapes with a few human figures. There are only a few narrative scenes. The closely set single shapes are flattened and laid out rhythmically on the surface. In contrast, the generally narrative panels from the railing and gate of the stupa of

Bharhut, Madhya Pradesh (c. 100 B.C.), are in a higher relief, the figures are as a rule more widely spaced, and the linear movement is more consciously organized and calm. The subjects illustrated are *Jātakas* (stories of the previous births of the Buddha). The reliefs on the square railing of Bodhi Gaya (1st century B.C.) further clarify the relation of figure and background. The inventiveness of the narrative relief on the gates of the Great Stupa at Sanchi is seen in the crowded grouping of its figures, mainly human, and in the effect of movement imparted by the light and shadow of its relatively high relief. Linear rhythms are no longer the main organizing factors. *Jātakas*, scenes from the life of the Buddha, and episodes from the history of Buddhism are of equal importance in suggesting the presence of the Buddha, who is not himself represented in any of the carvings.

Dating from this period (c. 1st century A.D.) also are colossal free-standing statues, representing yakshas (Sanskrit *yakṣa*), yakshis (Sanskrit *yakṣi*), and other pre-Buddhistic divinities, found in the Gangetic Valley and in central India. In these works naturalistic traits are given a static, cubical form. Two Jain images—one from Lohanipur, Bihar, possibly of earlier date, and the other a bronze figure of Pārshvanātha (Pārśvanātha) in the Prince of Wales Museum of Western India, Bombay—show the conventions which remained binding for Jain images of all periods, while the face of the bronze image forcefully portrays a visionary, ascetic type. A stone linga, or phallic symbol of Shiva (*Śiva*), in Gudimallam, Andhra Pradesh (c. 1st century A.D.), has an anthropomorphic image of the god in front. The low reliefs of the monastery in Bhaja (c. 1st century B.C.) are true rock sculpture spreading framelessly over the surface and continuing at a right angle on the adjacent surface. The quality of these traprock reliefs is purely plastic. The reliefs of the chaitya hall in Karli (early 2d century A.D.) owe as much to this west Indian mode of cave sculpture as to the north Indian school of Mathura, while the rock sculptures of eastern India (Udayagiri, Orissa) are related to the reliefs of the gates at Sanchi.

While the teeming torana reliefs of the Great Stupa at Sanchi were being carved in the 1st century A.D., the school of Mathura, under Kushana (Kuşāna) rule, evolved a sober style in which a few large figures were carved in graded relief planes. Anthropomorphic images of the Buddha and Bodhisattvas followed a change in Buddhist doctrine, answering a demand for images which another school in the Kushana Empire, that of Gandhara (Gandhāra) in what is now Pakistan, satisfied with the assistance of classical Western models. Mathura created a particular type of the Buddha image, a refined variety of its yaksha statues. The bodies of female figures, as in the yakshis of the Bhutesar railing, were modeled with sensuality. There is also a style of typological portraiture documented by examples and inscriptions. The statue of King Kanishka (Kanishka), for example, is a unique creation, combining indigenous modeling with planar discipline and trenchant outline. The wide-eyed heads of gray terra-cotta figurines from Mathura (c. 1st century A.D.) resemble the faces of Greek works between the archaic and classical periods.

In the 1st and 2d centuries A.D., the school of Amaravati (Amarāvati) in Andhra Pradesh decorated stupas with small-figured reliefs in grayish

white limestone, of which a few display the anthropomorphic Buddha image. Symbolic presentation and impassioned narrative are presented in a style of extreme elegance, whose sophistication transforms curvilinear movement and virtuoso modeling into expressions of the pathos of the fugitive festival of life. The style of Amaravati was in its formative stage in the 1st century and the beginning of the 2d century, when the reliefs of Jaggayapeta were being carved; reached its height in the middle of the 2d century; began to disintegrate at the end of the 2d century; and was continued in Nagarjunakonda (Nāgārjunakonda) in the 3d century and in Goli into the 4th century.

The monumental cave sculptures of Karli and the miniature reliefs of Amaravati were the great contributions of Indian sculpture of the period from the 3d century B.C. to the 2d century A.D. Sculpture in stone, however, comprised only a fraction of the plastic output. While none of the work in wood has survived, there is an abundance of terracotta figurines and plaques from the Ganges-Jumna Valley and elsewhere in northern India and the Deccan. These testify both to the essentially plastic quality of Indian sculpture and to the abstract and nearly unchanging religious art of the people. The only survivals of secular art are ivory plaques from Bagram, Afghanistan, whose style is related to that of Mathura and Amaravati and also exhibits a slight admixture of classical and Chinese elements.

Painting and Other Arts.—The art of painting was widely practiced in a gouache technique on a carefully prepared ground on cotton cloth, wooden boards, walls, and rock surfaces. Only some of the rock paintings still survive. The ceiling paintings of the Jogimārā Cave in the Ramgarh Hills of Orissa are related to the reliefs of Jaggayapeta, while the painted frieze on the left-hand wall of Cave No. 10, Ajanta, is closely connected with the Sanchi reliefs. All the resources of modeling in color, in line, and by shading were combined to produce a three-dimensional effect of plasticity.

The arts of the lapidary and the jeweler can be seen in the paintings, sculptures, and terracotta plaques of the period. Indigenous motifs were combined with Achaemenid and Scythian devices, and classical Western designs were used in Gandharan jewelry. Impressions of Western forms were also conveyed to India by coins and pottery (Roman coins and Arretine pottery, found at Arikamedu, Madras).

4TH TO 7TH CENTURY

Architecture.—Rock-cut sanctuaries, which had their small and simple beginnings in the 3d century B.C., attained their perfected form as Buddhist chaitya halls in the 2d century and as monasteries between the 5th and 6th centuries A.D. In these years about 1,200 cave sanctuaries came into existence. Except for approximately 100 Brahmanical caves and a few Jain excavations, they all served Buddhist worship and monasticism. Meanwhile, structural architecture in stone and brick began afresh in the 5th century, and before the 9th century had developed its principal types. Most of these buildings were Hindu temples. These new structural, stone-built sanctuaries were also adapted in rock-cut forms.

Buddhist Temples and Monasteries.—The form of the Buddhist rock-cut temple was perfected at Karli early in the 2d century A.D. In the following centuries it became a base for elaborate

sculpture. Carvings covered the triforium belt above the pillars; the wooden beams of the vault were copied in stone; and the stupa in the apse at the end of the hall gained in height and had a large image of the Buddha carved in front of it. The façade of Caves No. 19 and No. 26 at Ajanta (5th and 6th centuries, respectively) is still dominated by the central *gavākṣa*, but has a roll cornice above the first floor, while images of the Buddha take the place of the subordinate *gavākṣa*. In the last of the rock-cut chaitya halls, the Viśvakarmā Cave at Ellora (Elura; c. 7th century), the central *gavākṣa*, now of diminutive size, is relegated to the top of the second story of the façade, which is filled with large, rectangular windows as in a trabeate stone structure.

The viharas of this period far surpass the chaitya halls not only in number, but in development. They have a pillared porch in front of the hall, a regular row of monk's cells on the two sides, and, in the center of the far end, a small sanctuary flanked by one or two cells on either side. Whereas the earlier caves had no pillars, a colonnade runs on all four sides of the hall in the latest caves. (The earliest pillared cave, Ajanta No. 11, has only four pillars.) Ajanta Viharas No. 16 and No. 17 of the 5th century A.D. are excelled by Viharas No. 1 and No. 2, which were excavated about a century later. All four viharas have paintings on their walls, ceilings, and pillars. The pillars are surmounted by broad, fluted, amalaka (Sanskrit *āmalaka*, myrobalan) capitals.

Other Buddhist caves, such as those at Bagh, Madhya Pradesh (early 6th to early 7th century), add pillars of varied design in the center of the colonnade, while the viharas at Aurangabad, Bombay State (7th century), place the shrine conspicuously in the center of the hall. Two three-storied viharas in Ellora (Caves No. 11 and No. 12), with plain, square pillars on each story of their façade, have stately, sumptuous halls whose pillars are richly decorated with vase and foliage capitals.

One of the few structural monuments of Buddhism, the Dhamekh Stupa in Sarnath (c. 6th century), with its high plinth and drum, is remarkable for the richness of its abstract geometrical ornament alongside luxuriantly modeled lotus panels. Such contrasts in theme and sculptural execution, however, had been employed much earlier in Bharhut (c. 100 B.C.).

Hindu and Jain Temples.—Hinduism at first had no use for the large rock-cut interior, for it did not know congregational worship, nor did it in this period possess monastic orders. The first Hindu caves (early 5th century), in Udayagiri Hill near Bhilsa, Madhya Pradesh, are small, squarish shrines to which a structural stone porch has been added in front. Cave No. 3 in Badami (Bādāmi), Mysore (578 A.D.), follows the Buddhist example of having a pillared veranda, a hall, and a small sanctuary at the far end. Another cave at Badami is Jain (7th century). At Junagadh, Kathiawar, is an exquisite pillared hall whose use is unknown.

The apogee of Hindu cave temple design was attained in the 7th century at Ellora, where the walls of large halls are used for gigantic sculptures (Daśa Avatāra Cave). A small shrine with an ambulatory may be placed at the far end of the hall (Rāvaṇa kā Khāi and Rāmeśvara caves), or a transept may traverse the hall (Dhūmar Lenā Cave; c. 8th century). The most stupendous

of all the excavations is the spacious two-storied Kailāsa Temple (second half of the 8th century). Completely carved outside, it appears to rise between the vertical cliffs of its open-air ambulatory. A rock-cut version of the structured Kailāsanātha Temple in Kanchipuram, Madras (8th century), the Kailāsa Temple was itself repeated on a smaller scale in a Jain rock-cut temple, the Chhota Kailāsa of Ellora. Another masterly rock-cut temple is the unfinished Veṭṭuvānkoil, a Shiva temple at Kalugumalai, Madras (c. late 8th century). Of the same period are two large Jain temple halls, Indra Sabhā and Jagannātha Sabhā, Ellora.

The first structural stone temples are not impressive. The typical building is a small, square, flat-roofed shrine with a porch, either raised on a low plinth (Temple No. 17, Sanchi; 5th century) or surrounded by a covered ambulatory. It has either a small second story or a shrine on the second floor (Pārvaṭi Temple, Nachna Kuthara [Nacnā Kūṭhara], Madhya Pradesh, 5th century; Meguti Temple, Aihole, Mysore, 634 A.D.), or a small, more or less pyramidal, storied superstructure called a *sikhara* (Sanskrit *śikhara*; Daśa Avatāra Temple, Deogarh, and brick temple, Bhitargaon, Uttar Pradesh; c. 600 A.D.). Many varieties of these types are found in northern India and coexist in the southwestern Deccan. Two temples in particular, at Mahakut, Mysore (602 A.D.), represent early examples of the two main types of Indian temple architecture, the Nāgara or northern style and the Dravidian style. The Nāgara style, which is characterized by a curvilinear *sikhara*, is that of the majority of later Indian temples. The Dravidian style belongs to the south, and in one of its later, modified versions, called Vesara, to that part of Mysore where Mahakut is situated.

A few brick or stone temples (Ter, Bombay State; Chezarla, Andhra Pradesh; Durgā Temple, Aihole) are late examples of apsidal structures, whose design, developed originally to meet Buddhist needs, was adjusted to Hindu worship by dividing the sanctuary from the hall. A rock-cut version of this type is the Sahadeva Ratha in Mamallapuram (Mahabalipuram), Madras (first half of the 7th century), one of several small temples cut from granite in this part of the Pallava dynasty. These temples are miniature replicas of structural Dravidian temples. Except for the square Draupadi Temple with its square "dome," they simulate storied structures.

Sculpture.—Sculpture attained unequaled heights from the 4th to the 8th century. By means of subtly modeled planes and firm, flowing profiles, the Buddhist cult images of the 4th to the 6th century embody an inner spiritual realization. Iconographic formulas and facial traits are integrated in the plastic context, which is as sensitive as it is disciplined. Specific postures (*asana*; Sanskrit *āsana*), positions of the fingers and hands (*mudra*; Sanskrit *mudrā*), and supernatural signs (*lakṣaṇa*)—such as the cranial protuberance (*uṣṇīṣa*), elongated ears, webbed fingers, overlarge eyes behind lowered lids, and raised, arched brows conveying intensities of meditation, all of which indicate the more than human nature of the Buddha—serve as accents to stress the meaning of the overall plastic conception. Of the seated images of inwardly realized Buddhahood, that from Bodh Gaya (National Museum of India, New Delhi), which is assignable to the 4th century, is the earliest and most powerful. A

seated Buddha image from Sarnath (6th century), which shows the Buddha preaching his first sermon, has in its flawless balance a geometrical foundation of proportionate triangles and circles. In the latter respect, the image constitutes a *yantra*, a magical diagram in which the powers inherent in the deity are assigned to definite places in the design.

The Hindu sculpture of northern India, under Gupta rule, attained similar heights in the reliefs from Garhiwa near Allahabad, where the last residues of classical Western art are absorbed into a classical Indian art; in the stucco reliefs of the circular Nāga temple at Rajgir, Bihar; in the central Indian sculptures of Bhumara (6th century); and in the Daśa Avatāra Temple, Deogarh (c. 600). In their plastic sensibility these works give concrete form to subtle realizations of the path toward nirvana (Sanskrit *nirvāṇa*) or moksha (Sanskrit *mokṣa*).

In contrast, contemporary rock-cut sculptures of the Deccan embody the myths and potent presence of the great gods. The volume of the rocks adds its weight to the total impact of the sculptures, which have the timeless immediacy of cosmogonic powers. Superhuman in size and conception, the figures are based on an idea attainable only by perfect control of mind, emotions, and body through the discipline of yoga. Thus transformed in life, the figure of man is translated by art into a form adequate to the aims achieved through yoga. The body is conceived as a vessel filled by breath and kept in shape by the balance of inner rhythms which no external stimulus can deflect from their course. While this conception is also true of northern Indian sculpture, in the rock sculpture, particularly that of the Deccan, the figures also act out cosmic myths. They are the shapes of powers over life and death, whose deeds are performed in the stillness of withdrawal.

The northernmost and earliest outpost of gigantic mythical Hindu sculpture carved in the rock is the relief of the Varāha (boar) incarnation of Vishnu (*Viṣṇu*) on Udayagiri Hill, near Sanchi (beginning of the 5th century). Centuries lie between it and the ponderous compositions in the caves of Badami (578 A.D.), the eruptive power of the cave sculptures at Ellora (7th century), and the brooding satiation of those in Aurangabad (7th century). The greatest of all cave sculptures is the image of Mahādeva on Elephanta Island, near Bombay (c. 8th century), which is flanked by the majesty of other gigantic conceptions of the myth of Shiva. The Dhūmar Leṇā Cave in Ellora and the sculptures in Lonad are related to the style of Elephanta, while the sculptures of the Kailāsa Temple in Ellora (second half of the 8th century) have the svelte character of the south Indian idiom absorbed in the greater vision of Deccan cave sculpture.

The sharply defined quality of the rock-cut reliefs at Mamallapuram in south India (first half of the 7th century) is seen in the relation of architectural shapes and human figures; in the placement of the figures, some of them ideal "portraits," in large, rectangular panels; and in the adaptation of a mythical panorama to the entire surface of a rock. At the base of the relief called the *Kirātārjuniya* (*Penance of Arjuna*) was a pond which received water channeled through the grooves and projections dividing the composition. The sculpture of the relief was enhanced by the play of the water. When south Indian sculpture was brought into the Deccan in

the wake of political conquest in the 8th century, it imparted its own characteristics to the greater conceptions of the Deccan in rock-cut sculptures as well as in those which form part of structural temples (Virūpāksha Temple, Pattadakal, Mysore; after 740). The Deccan school of sculpture of the 7th and 8th centuries in turn made its influence felt to the north and the east (Sanchi, Rajim) at a time when the Gupta school had passed its zenith, and the local schools of Baroda, Gujarat, and Rajasthan had made their mark.

Painting.—The cave temples of the Deccan are also the repositories of classical Indian paintings (Ajanta Caves No. 9 and No. 10, beginning of the Christian era; Caves No. 16 and No. 17, c. 5th century; Caves No. 1 and No. 2, c. 6th century; Badami, 578; Bagh, early 7th century). These gouache paintings, mainly in earth colors, are laid out in panels that fill the walls or are continued from the one wall to another. The figures are crowded like those of a tapestry, and the paintings seem to project their contents toward the spectator. This illusion of the third dimension does not lead into depth. On the contrary, it releases the figures toward the spectator so that their impact is felt at the same time that their gestures and grouping relate them to the tapestry-like context in which they are linked by interlacing waves of movement.

A contemporary text, the *Viṣṇudharmottara*, describes the varieties of painting then practiced on walls, wooden panels, cloth, and other materials. Subject matter was both religious and worldly.

Minor Arts.—The subject matter of terracotta plaques, figures, and carved bricks of the 4th to the 7th century was as diversified as that of painting, and testifies to the use of these objects in both religious and residential buildings. Clay figurines and plaques were even more numerous, however, and the plasticity of Indian art owes much to the technique of modeling in clay. The high technical level of decorative art in these centuries is seen in the coins of the Gupta dynasty, in which classical Western and Kushana elements had become integrated.

HINDU ART: 7TH TO 15TH CENTURY

Architecture.—The development of Indian architecture from the 7th century on is concentrated in the Hindu temple built of stone or brick. Essentially, a Hindu temple consists of a sanctuary, generally square in plan, and its superstructure. Light falls through the door on the image of the deity or the linga of Shiva placed in the dark and small interior. While the thick walls of the interior are always unadorned, the outer walls of the sanctuary and the superstructure are elaborated in a variety of regional styles. The temple proper (*prāsāda* or *vimāna*; Sanskrit *vimāna*) with its small sanctuary (*garbhagṛha*) is the house and body of God. In front of the *prāsāda*, and placed coaxially with it, a porch and a hall (*mandapa*) or several halls may be added. Each of these has its own superstructure, which is lower than and different in shape from that of the *prāsāda*.

Nāgara Temples.—The leading temple type, the Nāgara, is found in all parts of India north of the Tungabhadra River. In a Nāgara temple a curvilinear superstructure (*sikhara*) rests on the four faceted walls of the sanctuary, and a broad buttress projects from the center of each of the three outer walls. While the interior is square,

Kulwant Roy

the exterior forms a stepped square or a stepped cross. The walls of the superstructure rise in parabolic curves from the sanctuary walls. The buttresses are continued along the curved slopes of the superstructure, which are gathered together toward the top. This truncated, curvilinear, trabeate superstructure terminates in a horizontal platform (*vedi*), surmounted in the center by a narrow circular neck that carries a flat, coggled stone (*amalaka*), which in turn is surmounted by a finial. The Nāgara type of temple, evolved in regional schools, was at its height from the 9th to the 12th century and continued into the 15th century, some of the latest examples being Jain sanctuaries in Rajasthan.

One of the earliest and simplest Nāgara temples is the Saṅgamaśvara Temple in Mahakut (c. 602); the Paraśurāmeśvara Temple in Bhubaneswar, Orissa (c. 7th century), temples in Osia, Rajasthan (c. 8th century), and the rock-cut temple in Masrur, Kangra District, Punjab (8th century) are variations of the same theme. In these shrines the sikhara and its buttresses are striated with stringcourses carved with miniature *garbhakṣas*, and its corners are punctuated at regular intervals by amalaka shapes. Rising from an indented cross of five, seven, or nine steps on each side, the central buttress is set apart by adjacent piers from the bulk of the building, whose carved facets rise tier upon tier in ascending planes.

Each of the three main regional schools of Nāgara architecture, those of Orissa, central India, and the northern Deccan, evolved a particular variety of sikhara and *mandapa*, while adaptations and subdivisions of these types are found in Rajasthan, Gujarat-Kathiawar, and the western Himalaya. Orissan architecture remained faithful to the original type as represented by the Paraśurāmeśvara Temple in Bhubaneswar. Where one or several *mandapas* are added in front of the *prāsāda* as places of rest and edification for pilgrims, the vertical and horizontal divisions of their walls correspond to those of the *prāsāda*. The superstructure of each hall is a low striated pyramid whose circular crowning members extend to an aliquot part of the height of the sikhara. The interior of these halls, which generally have no pillars, is lit dimly by latticed or perforated carved windows.

The number of facets of the superstructure increased from three in each direction in early Orissan temples to nine in later ones, and the total height from four (Paraśurāmeśvara Temple) to seven (Sun Temple, Konarak; 1238-1264) times the width. Each buttress is stepped in facets, so that the temple, from the plinth to the *vedi*, faces in all directions with its array of projections set off by the deep shadows of its recesses. The 9th century Mukteśvara Temple, Bhubaneswar, is the finest example of the Orissan style in its early maturity, while the Brahmeśvara and Liṅgarāja temples (c. 11th century) of the same city represent this style at its height. The sikhara of the Rājarañi Temple (11th to 12th century), however, is related to the central Indian style, while the Vaitāl Deul (8th century), with its wagon-vaulted tower, belongs to a widespread type represented mainly in the gate structures (*gopuram*) of south India. The wagon vault as well as the pyramidal tower characteristic of Dravidian architecture are found down to the 9th century also at various north Indian sites. Other Orissan shrines are built on a star-shaped plan, which in the 11th and 12th centuries was to become characteristic of

temples in the northwestern Deccan, but is found also at Nurpur in the Punjab. The regional specialization and logical development of a particular type are accompanied by anomalous types, which in turn may become the leading types of other regional schools.

In central India are found two distinct varieties of sikhara. On the first, which is similar to that of Orissa, the facets are extended beyond the *vedi*, which they surround with their pointed ends. The Mahādeva Temple, Nachna Kuthara (c. 8th century), is the earliest of this group, which comprises the temples of the Chedi and Chandella principalities. In Khajraho, capital of the Chandellas and a center of Nāgara architecture in the second half of the 10th and the 11th centuries, the other variety of the sikhara, of which the Kandariya Temple is the best example, was perfected. The sikhara here is actually a cluster of half and three-quarter sikharas, graded in height, which cling to its faces. The larger Khajraho shrines have an inner ambulatory with a wide, open, pillared balcony in the center of each face. The pillared hall in front of the temple is similarly open. High stone benches whose sloping backs project outward, their angle balanced by that of the projecting eaves above, frame the open spaces of the balconies. The *prāsāda* and its *mandapa* form a single architectural unit raised on a high terrace.

Sanctuaries built on a circular plan but otherwise conforming to the first variety of the Nāgara style are found in Uttar Pradesh in brick, having either a square *garbhagṛha* or a circular one, or in stone. The sikharas of temples in Rajasthan are of the clustered variety of the Nāgara style. Here an open pillared hall (*sabhā mandapa*) stands in front of the sanctuary with its hall. The white marble temples of south Rajasthan (Kumbharia; Dilwara, 11th to 13th century; Ranakpur, 15th century) have spacious pillared and domed trabeate halls.

Until about 1000 A.D., the temples of Gujarat and Kathiawar had either a pyramidal superstructure, as at Gop (6th century), or a Nāgara sikhara of the simpler type (temple near Thangadh or Than), and only rarely a sikhara of the clustered variety (Tarnetar), which later became the rule. With its open, pillared halls, ponds (Sun Temple, Modhera; 1026), wells, and gateways, the architecture of Gujarat and Kathiawar enhances the sumptuousness of the temples built on a star-shaped plan with an inner ambulatory and a two-storied *mandapa* (Ghumli; Sejakpur; Siddhapur).

The early Nāgara temples of the southern Deccan, with their curvilinear sikharas, rise alongside shrines with storied, pyramidal superstructures (Mahakut, Aihole, 6th to 7th century; Pattadakal, 8th century), while those in Alampur have Nāgara sikharas. The plan of all these temples, in which an inner ambulatory surrounds the sanctuary at the end of a rectangular pillared hall, is, however, typically south Indian.

In the northern Deccan a third variety of Nāgara sikhara combines offsets ascending in the four directions with horizontal, parallel arrays of miniature sikharas placed between the four piers (Nilakanthesvara Temple, Udayapur; 1059-1080). The plan is generally star shaped. Still other varieties are found in Bengal and in the western Himalaya.

Dravidian Temples.—In south India the Dravidian style develops in a straight line from

the monolithic raths (rathas) at Mamallapuram (first half of the 7th century) to its culmination in the Brihadiśvara (Brhadiśvara) Temple in Tanjore, Madras (c. 1010). The offsets of a Dravidian temple, which are relatively thin pilasters placed on a straight wall, do not extend to the superstructure, whose pyramid is articulated horizontally by false stories. On each story cells surround the walls of a central block. In the early temples an open-air ambulatory divides the cells or miniature shrines from the walls in the center, but beginning in the 8th century the rows of shrines, reduced in size and increased in number, cling to the body of the pyramid, which is crowned by a circular or polygonal dome shape surmounted by a finial. After the 11th century the pyramidal gate structures (gopuram) rise to a greater height than that of the sanctuary. Flat-roofed, open-pillared halls fill the temple precinct.

In the southern Deccan a mixed style of predominantly Dravidian elements, which was in process of formation from the 8th century on, reached its height in Mysore in the so-called Hoysala style with its star-shaped, many-shrined temples (Keśava Temple, Somnathpur; c. 1268). In all styles the door of the sanctuary is ritually and architecturally next in importance to the image in the *garbhagṛha*. The architectural and sculptural features of the door are enhanced by the porch in front of it and by its superstructure, which is attached to that of the *prāsāda* and connects it with that of the *maṇḍapa*.

Sculpture.—Sculpture is essentially part of the Hindu temple, which itself is monumental sculpture when viewed from the outside. The separately carved steles in the niches of the buttresses are cult images subject to iconographic rules, whereas the majority of the figures, carved almost in the round, and the relief compositions express the meaning and kinetic impact of the temple walls. While figure sculpture predominates on the perpendicular walls, the superstructure is enhanced by abstract architectural sculpture whose rhythmical sequences and graded scale correspond to the disposition of the figures of gods on the walls and plinth.

The schools of sculptures are even more diversified than the architectural styles; there are, for example, considerable differences between the Chandella and Chedi schools of central India. Iconographically, each figure and each motif have their definite place on the temple and their definite meaning. Artistically, the norm serves as the basis for subtle and infinite variations on the given themes. Besides temple sculptures in stone, brick, and wood (Brahmaur, Himachal Pradesh, c. 700; carved door, National Museum of India, New Delhi), metal statues of Buddhist divinities were cast with equal competence from the 3d century in Andhra Pradesh (Nagarjunakonda; Amaravati, 6th century); in central India (Srirpur, early 8th century); in Bihar (Nalanda, Kurkihar); and in south India (Negapatam, c. 9th to 16th century). The large Hindu images of Chamba, Himachal Pradesh (c. early 8th century), on the other hand, are surpassed only by those of south India. There, in addition to images of divinities, are found idealized portrait statues of saints and royalty not only in bronze, but also in stone on the temple walls (Nagesvaraśvāmi Temple, Kumbakonam, Madras; c. 9th century).

Painting.—In the ceiling paintings of the Kailāsa Temple, Ellora (late 8th century), the classical tradition of Ajanta was in process of

being superseded by an emphatic linear style of pointed angles and flat color surfaces. Beginning in the early 12th century the new linear style was to become the leading mode of Indian painting. Centered in the western part of the subcontinent, it was used pre-eminently in the illustration of Jain books made of palm leaves and, from the 15th century, of paper. By this time, Hindu and secular subjects were also painted as book illustrations and on scrolls (*Paśanta Vilāsa*, 1451; Freer Gallery of Art, Washington, D.C.). This style also spread to Uttar Pradesh (ceiling paintings of a Vaiṣṇava temple hall in Madanpur, 12th century; Jaunpur) and to central India (Mandu, Madhya Pradesh). Meanwhile, the classical tradition was continued in south India (wall paintings of the Brihadiśvara Temple, Tanjore; c. 1010) and in Bengal (Buddhist palm-leaf scriptures).

ART FOLLOWING THE MUSLIM IMPACT: 13TH TO 20TH CENTURY

Architecture.—The Muslim impact made itself felt in Indian art beginning in the 8th century, but only in the 13th century did a distinctive Indo-Muslim architecture develop. When the Muslim conquerors set up their mosques in Delhi (Quwwat-ul-Islām Mosque; 1195–1199) and Ajmer (c. 1205), they used the pillars of Hindu temples. Whereas the Hindu temple is centered on a cubical sanctuary housing the image or symbol of a god and achieves monumentality by means of its superstructure, the mosque, a pillared cloister whose west side indicates the direction of Mecca, is screened by a façade, and its central space is surmounted by a dome. The true arches of the façade and the squinch system supporting the dome are technically different from the trabeate indigenous construction, just as the spacious interior of the mosques and tombs, the contrast of flat walls without figure sculpture, and the volume of domes and minarets differ from Indian temple architecture.

The most outstanding early Muslim monument is the Qutb Minār in Delhi, a five-story tower of fluted red sandstone from which the faithful were called to prayer. The original four stories, each differing in section and in the bands of inscriptions surrounding it, rise in perfect proportion from a diameter of 46 feet at the base to one of 10 feet at the top. Carved inscriptions used as mural decorations also distinguish the tomb of Iltutmish (Altamsh; 1235), a king of the Slave dynasty. To the succeeding Khalji dynasty (1200–1320) the architecture of Delhi owes both the combined use of red sandstone and white marble and the keel-shaped arch. The buildings of the Tughluq dynasty (1320–1414), with their massed volumes of sloped, unornamented sandstone walls and marble Tatar domes (tomb of Ghiyas-ud-Din Tughluq), occasionally incorporate an Indian motif (amalaka; pot finial). The multitude of tombs erected in Delhi under the Sayyid (1414–1451) and Lodi (1451–1526) dynasties range from a cenotaph within an open pillared pavilion to cloister garths surrounding colonnaded octagonal or square monuments.

While successive dynasties left their mark on the architecture of Delhi, regional Indian styles made their contribution to the requirements of an alien cult and to the imported forms of its sanctuaries and civic buildings. After the tentative solution of the Jāmi' Masjid in Cambay (1325), the school of Gujarat created the unrivaled Jāmi'

Masjid of Ahmadabad (1423). The façade of the mosque, with its pillared portico flanked by airy screens and arches that contrast with the solidity of the buttresses and minarets, leads into a two-storied hypostyle hall of closely set pillars as in a temple *mandapa*. Later Ahmadabad mosques have closed façades with minarets on each side of the central archway or open façades with minarets at their ends. The perforated screens of the Sidi Sayyid Mosque (c. 1515) are unexcelled.

In Malwa, in what is now Madhya Pradesh, a local style based on the Tughluq and Lodi architecture of Delhi was used at Dhar and Mandu in the 15th century in religious and secular buildings with polychrome surfaces of stones and glazed tiles. Derived from these are the buildings of Chanderi, which, with the addition of Ahmadabad elements, in their turn influenced (and were surpassed by) the Hindu palaces of Bundelkhand.

In the Deccan the Delhi style was reinforced by contemporary Persian elements, but the architecture of the courts of Gulbarga, Bidar, and Golconda cannot equal the Adil Shahi style of Bijapur, of which the Gol Gumbaz (mid-17th century) is the crowning achievement. Above its

mausoleum of Humayun in a parklike enclosure at Delhi (begun in 1564), an Indian interpretation of a Persian theme, antedates Emperor Akbar's fortress-palace in Agra (1566), which was based on the Hindu Man Singh's palace at Gwalior (c. 1500); and the new capital city, Fatehpur Sikri (founded 1569), with its Gate of Victory (Buland Darwaza; 1596) of the Jāmi' Masjid and its palaces of varied styles. During the reign of Emperor Jahangir, Akbar's mausoleum was completed in its garden setting in Sikandra (1613), and the white marble mausoleum of I'timād-ud-Daulā was inlaid with precious stones in its formal garden at Agra (1626). The latter has greater solidity than the dreamlike marble buildings of Shah Jahan (r. 1628–1658) in the Red Fort at Delhi, but it was that emperor who built the unrivaled Taj Mahal (Tāj Mahall) in Agra. The reign of Shah Jahan is also known for landscape architecture, which comprises both gardens without buildings, as in Srinagar, Kashmir (Shalimar, Nishat Bagh), and a combination of artificial lake and pavilion, in Ajmer, Rajasthan (Ana Sagar).

While Mughul architecture passed its zenith in the reign of Aurangzeb (Moti Masjid, Delhi; 1662), indigenous architecture contributed the carved brick temples of Bengal (Vishnupur; 16th to 18th century), the wooden buildings of Kerala, the Hindu palaces and stone houses of Rajasthan, and the carved wooden houses of Gujarat and the Punjab. Meanwhile, palaces erected in the south remained faithful to the south Indian tradition of storied pyramidal superstructures until, in the 18th and 19th centuries, Western influence produced not only architectural hybrids but also colonial buildings of quality. The British attempt of building New Delhi (inaugurated 1931) as a self-contained architectural unit was followed in the 1950's by the construction of Chandigarh, the new capital of the Punjab, by Le Corbusier and other foreign architects.

Sculpture.—The carved images of Hindu temple walls lost some of their importance under the rule of iconoclastic Islam, while new trends appeared within the traditions of Indian sculpture. In northern India the development of the linear style of painting described above preceded that of a school of sculpture in which the flowing sinuosities and subtleties of modeling were reduced to clear-cut masses laid out in angular planes. Except for the reliefs of the Hazara Rāma Temple in Vijayanagar (1514), south Indian stone sculpture of the period is of iconographic interest only. From now on painting displaced sculpture as the leading Indian art form.

Painting.—The western Indian school of painting had reached heights of refinement in the illumination of palm-leaf texts in the 14th century, and in the following century these were transferred to paper in glowing colors. The 16th century is of crucial importance in the history of Indian painting. The innumerable illustrations of Hindu myths, poems, musical modes (*rāga*), and other texts and the full-page album leaves that were the delight of princely and scholarly patrons for the next three centuries are seen in their initial stage, in which Persian (Shiraz), western Indian, and classical Indian styles are combined, in the *Nīmat-nāma* (Mandu; c. 1505). A similarly sprightly combination of styles enlivens the paintings of the *Tarīf-i-Hussain Shāhī* (Ahmadnagar; c. 1565–1570) and the *Nujum-al-'Ulūm* (Bijapur; c. 1570). Some of the zest of this

Werner Bischof from Magnum

Open-air observatory at Jaipur, built in the 18th century.

cubical walls rises a hemispherical dome with an external diameter of 144 feet, which spans one of the largest interiors in the world by means of a unique system of intersecting arches.

The builders of the mosques of Pandua (14th century) and Gaur (16th century) in Bengal utilized the carved black stones of Hindu architecture, while in Kashmir a local timber architecture (15th century) succeeded the earlier stone temples and was employed until the Mughul emperors introduced their own stone buildings. At Sasaram, Bihar, one of the greatest Indian Muslim buildings was erected about 1540 by Sher Shah, the Afghan king of Bengal and Delhi. This terraced mausoleum, which rises majestically from an artificial lake, honors the name of Sher Shah, as he had wished, "to the day of resurrection."

Like Sher Shah's mausoleum, the buildings of the Mughuls record patrons' aspirations in architectural terms. The red sandstone and marble

formative century appears also in south India in the wall paintings of Lepakshi (Vijayanagar school), while in north India a residual western Indian style formed the stem on which pre-Mughul Persian and Mughul elements were grafted. Thus richly nourished, new schools of charm and vitality developed in Rajasthan and central India. Painting under the Mughuls reflected the personality of the successive rulers. Persian, Indian, and European influences were combined in a school of miniature painting whose portraits are its noblest contribution.

Evolving independently from their pre-Mughul past, other Indian styles of painting were conceived on a larger scale than the miniatures of the Mughuls. Even though their actual format is generally that of an album page, the width of their spacing carries both epic and lyrical themes. The central Indian schools were the most important in the 16th century, and those of Rajasthan in the 17th and 18th centuries. Meanwhile, new schools developed at the western Himalayan courts following the disintegration of the Mughul court at Delhi. In such centers as Basohli in Kashmir and Kangra in the Punjab, a new vitality and profound religious experience were expressed in ever-fresh variations of style.

European influence produced the so-called East India Company paintings of Patna (18th to 20th century) and the popular bazaar style of Kalighat (Calcutta; mid-19th to early 20th century), and an infinitely varied folk art formed the background for painting as practiced in the Westernized cities of Calcutta, Bombay, Delhi, and Madras. In the 20th century three painters—Abanindranath Tagore (1871–1951), Jamini Roy (1887–), and Mohan B. Samant (1926–)—may be considered typical of the development of modern Indian painting in its conscious looking back to Indian tradition combined with the integration of contemporary Western styles.

Minor Arts.—The crafts, especially those of textile and jewelry design, responded to the stimuli of Mughul court life. In the 20th century, however, they were affected by the changes of the machine age.

8. DANCE, MUSIC, AND DRAMA

The arts of the dance, music, and drama have always been interrelated in India. Dancing and music share a common literature and a common term, *sangita*, and both are integral parts of the traditional drama.

Dance.—The dance was known in ancient India chiefly in a religious environment or as expressing religious themes, and even in the modern revival of Indian dancing the themes are largely those of religion. Among the artifacts of the Harappa civilization in the Indus Valley (c. 2500–1700 B.C.) is a bronze figurine of a female dancer. In the Rig Veda (*Ṛgveda*) the

goddess Uṣas (Dawn) is described as a brightly attired danseuse (RV 1: 92, 4). The Hindu epics *Mahābhārata* and *Rāmāyaṇa* and Buddhist literature show that not only was the art popular, but its chief exponent, the courtesan, was part of contemporary society and court life. The dramatist Kālidāsa was thoroughly acquainted with the technique of the dance, which is an important motif in one of his plays. In the Indian view, drama cannot be divorced from the dance, and the earliest treatise on the former, the *Nāṭya-śāstra* of Bharata, is also the basic authority for the latter.

In his work, Bharata describes two types of dance: the graceful, lyrical type called *lāsya*, and the forceful type called *tāṇḍava*. The *lāsya*, which is presented by a single danseuse, consists of 10 or 12 detached emotional themes. The *tāṇḍava* comprises 108 *karanas*, poses associated with the god Shiva (*Śiva*), each of which is determined by a particular disposition of the hands and feet. A selection of 2, 3, 4, or more *karanas* in a particular sequence is a dance composition called an *aṅghārā*. Such dances, significant only for the beauty of their motion, are known as *nṛtta*; a dance which portrays and interprets human emotion is called *nṛtya*.

While rhythmic movement and the expression of emotions or ideas are found in the dances of all countries, in the Indian dance the steps and the motion of the limbs follow specific *tālas* or rhythmic measures, which are improvised into varied patterns and tempos worked into different designs with crescendo endings. Moreover, the expression of emotions and ideas is presented through large physical movements (*aṅgika*); subtle facial expressions (*upāṅga* or *mukhaja*); and hand symbols, called *hastābhinaya* or *mudra* (Sanskrit *mudrā*), which interpret, word by word, the meaning of a song or poem.

The greatest early writer on the dance after Bharata was Kohala, who codified many minor forms not noted by the former. Expositions of Bharata's text were written by Śrīharṣa, by a Buddhist named Rāhula, and, between the 9th and 11th centuries, by a number of savants in Kashmir. At this time the tradition of the dance was also actively cultivated in Malwa, where King Bhoja of Dhar was the most important writer; and in Mithila (northern Bihar), where Nānyadeva composed a lengthy commentary (*bhāṣya*) on Bharata. Western India then embraced the subject, and rulers of the Chalukya and Yadava dynasties and writers patronized by them contributed excellent expositions of the art. In Andhra, Jāyasaṃpati wrote a very useful work, *Nṛttaratnāvalī*. The center shifted in the 17th and 18th centuries to Tanjore, where south Indian music and dance reached its highest development. In Kerala dance dramas served to keep the art alive. Meanwhile, the dance continued to be fostered in the north, particularly in Mewar, Bihar, Bengal, Assam, and Orissa, where a number of valuable treatises were written. There are also texts ascribed to gods and sages, of which the most important is the *Abhinayadarpaṇa* (*Mirror of Gesture*) of Nandikeśvara, used in all parts of south India. Among materials in regional languages, those contained in the Tamil epic *Siḷappatikāram* (*Lay of the Anklet*) and its commentary by Adiyārkkunallār are the most noteworthy. Sources for the study and reconstruction of the Indian dance do not lie only in such books: even greater aid is to be had from painting and

sculpture, as in the Amaravati Stupa and the temples of Chidambaram and Tanjore. Of still greater value is the living tradition of the Indian dance in Southeast Asia, where much that has been lost in India itself can be recovered.

From these and other sources we know of a number of forms and compositions. The *lāsya* continued to be the solo feminine dance par excellence, now represented by the south Indian nautch. In addition, a form with a continuous story was composed for solo dancing and gesticulation. Other forms are known from the plays, from the commentary on the *Nāṭyaśāstra*, and from Bhoja's *Sṛṅgāra Prakāśa*. In most of these a love theme is interpreted by one or more dancers. Some of them (for example, the *prasthāna*) employ intricate dances; some, such as the *ḍombī*, use such special instruments as a miniature drum; and some, among them the *bhāna*, display the gaits of different animals. The *rāsaka* comprises a variety of designs composed by two or more dancers. There are also many regional dances described in later works. Among these are the *gondālī*, taken from the hunters of Maharashtra. The *kollāṭa* is an acrobatic dance. The *kandukanṛtta* employs a ball. The *cindu* is a Dravidian dance mode, and the *jakkani* originated in Iran. The *śābaranṛtta* is a hunter's dance, the *kuranvañci* is a gypsy dance, and the *karakam* is a religious dance performed with a pot on the head. As the art developed, fresh movements and poses were adopted from different regions (*deśī*). Among the new regional elements were many jumps (*utplutī*), which were not previously known.

In modern India the art of the dance lives in the following principal forms: the nautch or *Bharata nāṭya* of the south, chiefly Madras; the *kathakālī* of Kerala; the *kathak* of the north; and the *manipūrī* of Assam. The nautch and the *kathak* are related lyrical solo dances. The former has Andhra, Kannada, and Tamil styles, the last now being popular in all parts of India. Dominating all forms is the 12th century masterpiece of Jayadeva, the *Gītagovinda*, which inspired many of the regional types of dance.

In most solo dances the emotion portrayed is love centering around a god, often Krishna (*Kṛṣṇa*); such love implies the spiritual yearning of the individual soul for the Supreme Soul. Devotional cults (*Bhakti*) in various areas have proved an inspiring force of the art.

See also separate article on DANCE—*Historical Beginnings*.

Music.—The earliest form of Indian music is found in the *Sāma Veda*, a musical treatment of the hymns of the *Rig Veda*. A special priest, the *udgātṛ*, sang the hymns at the sacrificial ceremonies, and they were also sung as mystic exercises believed to bestow spiritual benefit on the singer. This religious theme is a basic characteristic of Indian music, and throughout its history its greatest exponents have been saints.

The *sāman* (chant) was sung in a descending series of notes. In the beginning only three or four notes were employed; later the fifth, sixth, and seventh notes also were used, but the two last occur very rarely. According to the oldest theoretical authority, the *Nāradaśikṣā*, the *sāman* takes the secular flute notes in the order *ma* (*madhyama*), *ga* (*gāndharva*), *ri* (*ṛṣabha* or *riśabha*), *sa* (*śaḍja* or *śaḍja*), *dha* (*dhaivata*), *ni* (*niśāda* or *niśāda*), *pa* (*pañcama*). Vedic literature refers also to a large number of musical instruments, including stringed instru-

ments, flutes, cymbals, drums, and, most important of all, the *vina* (Sanskrit *vinā*, lute).

The second stage of Indian music is marked by heroic lays and epics—*akhyānas* (Sanskrit *ākhyāna*) and *itihāsas*—which minstrels (*sūtas*) recited to the *vina*. The third stage is represented by the sacred *mārga* or *gāndharva* music, which represented songs on Shiva sung to melodic patterns or scales called *jātis*. From the seven *svaras* (notes) three basic groupings called *grāmas* were formed. The high-pitched *ga-grāma* went out of vogue very early, and all the *jātis* in which the epics and early *mārga* songs were sung were derived from *ma* and *sa*. Later *ma-grāma* also declined, and all the melodies of modern Indian music are derived from *sa-grāma*. Out of the *jātis* developed the *rāgas*, the later large body of melodies characteristic of Indian popular music.

The first elaborate treatise extant is the *Nāṭyaśāstra*, in which music is described as an accessory of the dance and drama. Among the topics discussed are instruments, the melodic system, the 22 *srutis* (Sanskrit *śruti*, microtonal interval), the *ma-* and *sa-grāmas*, the 18 *jātis* (7 from each *grāma* and 4 mixed ones), the appropriateness of various notes and *jātis* for different emotions, and the songs (*dhruvās*) used in different situations. The most important later text is Mātanga's *Bṛhaddeśī*, which is the first to classify the *rāgas*.

The most noteworthy factor in the later history of Indian music is the growing distinction between the north Indian and south Indian schools (now known as Hindustani and Carnatic, respectively), which began in the Muslim period. While the fundamentals remained the same in both schools, stylistic differences developed. Moreover, the southern school assimilated features of the art characteristic of south India from the earliest times, some conception of which may be gleaned from the epic *Silappatikāram* and the Shaiva and Vaishnava psalms associated with south Indian temples. Since the south was comparatively free from outside influences, the southern school preserved the art in a purer form, although it is clear that the northern school preserved certain other aspects of the tradition. In general, the northern school permits greater freedom, and the southern observes stricter standards, in expounding the *rāgas*.

In contrast to Western music, which is harmonic, Indian music is melodic and depends for its appeal on a linear succession of notes. A note in Indian music is not a fixed point, however, but lies somewhere within an interval. The Indian singer does not hit a note exactly, but often approaches it with grace (*gamakā*), glancing or hitting another note slightly. The term *rāga* or *rakti*, which is used for melody or melodic sweetness, has an emotional connotation. The *rāga* system is notable not only for its variety and richness, but also for the play of imagination and improvisation developed in expounding the *rāga* within its accepted outline. A *rāga* can be expounded through a literary composition or by itself (*ālāpa*); in the latter method, in particular, it develops a poignant quality and has been valued for the mental concentration and spiritual absorption it induces. Since a *rāga* is to be understood in relation to a constant basic tonic (*sruti*), all Indian music is sung with a drone. Other distinguishing characteristics of Indian music are its rhythmic variety, which is derived from a system of 108 different *tālas*; and its many instruments.

Of special significance among Indian musical compositions at the end of the classical age is the *rāga kāvya*, a continuous poem sung in one or more *rāgas*; it is to this class that the *Gitagovinda* belongs. Under the influence of this work a number of musical poems and plays were created in various parts of India. There were also a large number of compositions called *prabandhas*, which employed either Sanskrit or the regional languages.

Following the development of northern and southern schools, distinctive forms of compositions arose in each area. The *dhruvād* is the most dignified and austere composition of the north; others include the *dharmar-hori*, *kheyāl*, *thumri*, *tappa*, and *tarana*. In addition, there is a vast body of northern devotional songs (*bhājans*). Among the basic composition forms of the south are the *lakṣaṇagita*, a grammatical composition for practice; *varṇa*, of both grammatical and artistic value; *kīrtana* and *kṛtī*, which are purely artistic; *paḍas*, both devotional and erotic; *jāvalis*, light love compositions; and *tillānas*, rhythmic pieces. These are in the Telugu, Sanskrit, Tamil, Kannada, and Malayalam languages.

See also separate article on MUSICAL INSTRUMENTS.

Drama.—Sanskrit drama must have been well developed by about 500 B.C., for the great grammarian Pāṇini refers to two aphoristic texts of acting, the *Naṭasūtras*. The minister-poet Subandhu, who lived at the court of the Mauryas in the late 4th and early 3d centuries B.C., wrote a play, the *Vāsavadattā Nāṭyadhārā*, a fragment of which survives in quotation. In a series of acts within acts he combined a court intrigue with the romance of King Udayana. The technique employed here shows that various forms of drama had developed before Subandhu's time. The celebrated Bhāsa was probably the leading dramatist before Subandhu. In the plays discovered in 1910 and ascribed (controversially) to Bhāsa, tense situations are developed in a simple technique and language. The best of them is the *Svapnavāsavadattā* (*Vāsavadattā Seen in a Dream*), based on the Udayana story. Evidence of a flourishing theater in the 2d century B.C. is found in the *Mahābhāṣya* of the grammarian Patanjali. The discovery of fragments of the play *Sārīputraprakaraṇa* by the Buddhist poet Aśvaghoṣa among the Buddhist manuscript remains in Turfan points to the same conclusion.

The outstanding Sanskrit dramatist was Kālidāsa (fl. 5th century A.D.), who wrote three plays. *Mālavikāgnimitra*, a play of the graft type called *nāṭikā*, tells the story of the love of King Agnimitra and Princess Mālavikā, who lives incognito in his harem as a gifted dancer. In the *Vikramorvaśīya* (*Urvaśī Won by Valor*) there is an unrivaled scene in which the hero raves in a forest after his beloved has disappeared. Kālidāsa's masterpiece, as indeed of all Sanskrit literature, is the *Abhijñānaśākuntala* or *Sakuntalā*, whose contrast of sylvan settings with court life and delineation of character and sentiment are superb. Nature and the human heart are unified by the poet, who also develops an underlying philosophy of love.

The outstanding example of a social play (*prakaraṇa*) is the *Mṛcchakaṭika* (*The Little Clay Cart*) by King Śūdraka (Śūdraka) of uncertain date. Acute characterization, a combination of realism and idealism, and much genuine humor make it highly stageworthy. A poet sometimes

likened to Kālidāsa, particularly as a master of pathos, is Bhavabhūti, who lived about 700 A.D. His *Uttararāmacarita*, depicting the later life of Rāma, touches the heart with its pathetic scenes. A successful play on the same theme is the *Kundamālā* (*The Jasmine Garland*) of King Dhiraṇāga. Bhavabhūti's *Mālatīmādhava* is a partially successful play of the type of the *Mṛcchakaṭika*. King Harsha (Harshavardhana) of Kanauj (r. 606–647 A.D.) was the author of three plays: the *Priyadarśikā* and the *Ratnāvalī*, of the same type as the *Mālavikāgnimitra*; and the *Nāgānanda*, which broke new ground by depicting as its chief theme the self-sacrifice of the hero in saving the life of a serpent (*nāga*). Another prince, Viśākhadatta, wrote two remarkable plays, one on a purely political theme called the *Mudrārākṣasa*, which employs friendship as an important motif; and the other, a political play turning on love, the *Devicandragupta*. Meanwhile, Sanskrit drama was cultivated in south India by King Mahendravarikrama Pallava of Kanchi, who wrote two farces: the *Mattavilāsa*, making fun of heretical sects; and the enjoyable *Bhagavadaj-jukīya*.

Like the *Rāmāyaṇa*, the *Mahābhārata* inspired many plays, including the *Mukāṭāḍika* of Bāṇa, the *Pārthaviyaya* of Trilocana, the *Pāṇḍavānanda*, and the *Venīsaṃhāra* of Bhaṭṭa Nārāyaṇa. Bhimaṭa, a Kālajāra prince, wrote five plays, of which the best, the *Svapnadaśanana*, is related to the *Rāmāyaṇa*, and the *Manoramāvatsarāja* exploits the Udayana cycle. By far the best of these plays yet to be discovered is the *Puṣpadūṣitaka*, a masterly social drama. Among other notable authors of heroic plays are Murāri, known for his *Anargharāghava*; Rājasekhara (fl. early 10th century), whose *Karapūramaijari* (*The Camphor Garland*), a play of love, music, and dance, was written entirely in Prakrit; Śaktibhadra, author of *Ācāryacūdāmaṇi*, and Kulasekhara, author of *Subhadrādhanañjaya*, both of the south; Kṣeṃśvara (fl. 10th century), who wrote *Caṇḍakaṇṭhika* and *Naiṣadhañanda*; and Jayadeva (fl. 12th century), author of *Prasannaṛāghava*. Other types of plays are *bhāṇa*, monologues of love and city life; and allegories representing different schools of thought. In the postclassical period, when minor courts in various parts of India actively fostered Sanskrit, there appeared many specimens of the shorter farce, amorous monologue, and heroic encounter, as well as plays on the lives of saints, local rulers, and temple legends.

The Indian technique of production is idealistic and symbolical and sets little store by extraneous stage settings. The earliest Sanskrit text on the theory of drama is the *Nāṭyaśāstra*, which covers the entire art of the theater, including proper buildings, make-up, language, prosody, poetry, plot and its construction, characters, speech and styles of acting, stage conventions, dance, and music. Drama (*nāṭya* or *rūpaka*) is defined as imitation (*anukāra*) or representation (*anukīrtana*). Three types of playhouse—rectangular, square, and triangular—are described, and 10 major types of drama and a derivative type are discussed: the heroic *nāṭaka*, the social *prakaraṇa*, a graft of the first two types (*nāṭikā*), the farce *prahasana*, the amorous monologue *bhāṇa*, the heroic encounter *vyāyoga*, the heroic *ḍima*, *samavakāra*, and *aṅka*, and the social *vīṭhi*. Plot is to be conceived in five stages (opening, progression, development, pause, conclusion), which

are brought about by the simultaneous development of the five elements of the story (seed, continuity or recurrent motif, major and minor helpful episodes, purpose) and the five stages of the action (beginning, effort, hope, certainty, fruition). Both plot and character are subservient to emotion, for the distinguishing mark of Indian drama is the theory of *rasa*, or the evocation of an emotional response in the spectators, who thereby attain serenity and repose (*vīśrānti*).

As time passed, music and dance became more prominent elements in the drama, and folk dances also inspired classical authors. These two trends enlarged the repertoire of the Indian stage with a score of new forms in operatic, dance-drama style, which were codified and described as *uparūpakas* (minor stage forms). The *uparūpakas* linked the classical and the popular theater, which developed in regional languages and gained fresh momentum from the Bhakti movements: the *yātrās* of Bengal; the *āṅkīa nāts* of the Vaishnava centers of Assam; plays of Bihar and Nepal mixing Sanskrit and local languages; the *bhāvai* of Gujarat; the *lālita* of Maharashtra; the *yak-ṣagāna* and *bhāgavata nāṭakas* of the Telugu, Kannada, and Tamil regions; and the *kṛṣṇāṭṭam* and the *kathakali* of Kerala.

With the advent of British rule and the establishment of English colleges and the universities, the realistic English stage was adopted in India. For a time there was vehement criticism of the indigenous technique, but with the support of Rabindranath Tagore, Indian authors soon woke to the beauty and value of the traditional theater, which attained a new vogue. In the 20th century both types of theater have flourished. Private efforts have been supplemented by those of the Indian government, which in 1952 founded the National Academy of Dance, Drama and Music.

9. LANGUAGES

Subcontinent of India.—The Indian subcontinent—politically divided since 1947 into the nation states of India and Pakistan—harbors, according to the last fully utilizable linguistic census (that of 1931), 141 different languages. As of 1951 censuses, these were spoken by a population of 438 million. Of the total, 78 languages have less than 20,000 speakers each (12 of these, less than 1,000). Only 26 languages can boast of more than half a million speakers. The rest, 115 languages, are distributed over not quite 2 per cent of the population, most of them being border infiltrations. Occasionally they constitute delicacies for linguistic specialists (such as the mysterious Burushaski, spoken in northern Kashmir by about 26,000 persons, which seems to be isolated among the languages of the world), but politically, economically, and culturally they have no more significance than the scores of American Indian languages spoken in the United States. The linguistic diversity of the subcontinent appears not greater but smaller than that of Europe, which is approximately comparable in area and population. According to the census of 1931, there were only four language families of more than 1 million speakers each: Indo-Aryan languages, 254 million; Dravidian languages, 72 million; Munda

languages, 5 million; and Iranian and Dardic languages, 4 million.

Indo-Aryan languages are spoken throughout the northern and central parts of the subcontinent as far as the Deccan. They extend farthest south in the west, the southernmost dialect being Konkani (belonging to Marathi), which is spoken on the west coast even below Goa. All these languages descend from a single language (divided early into a western and an eastern dialect), of which we have the earliest literary form (2d millennium B.C.) in the Sanskrit of the Rig Veda (*Rgveda*); transitional stages are given in the Middle Indic dialects (Pali, Prakrit, Apabhramsa). Genealogically, Sanskrit is closely related to Old Iranian (Avestic, Old Persian) and, together with it, forms part of the Indo-European family of languages.

Iranian languages are spoken in Baluchistan and along the northwestern frontier. The Dardic languages, spoken in Kashmir and Afghanistan, form a transitional stage between Indo-Aryan and Iranian.

Dravidian languages occupy the territory south of the Indo-Aryan languages and are found also in some enclaves within their domain, particularly in the eastern part of northern India. An exception is presented by Brahui (218,000 speakers), which is spoken in the farthest northwest within the area of Baluchi. This language is of the greatest historical interest, for its situation seems to show that an original continuum of Dravidian languages was broken up either by migration or by intruding foreigners (possibly the Indo-Aryans). The Dravidian language family cannot be connected genealogically with any language outside the subcontinent.

The Munda languages are scattered as enclaves in the southeastern area of Indo-Aryan speech. Together with the language of the Nicobar Islands, they may belong to the Mon-Khmer (Austroasiatic) language group.

Republic of India.—The Indian Constitution of 1950 made Hindi the official language of the republic, after 15 years to replace English, which was retained temporarily as an administrative vehicle. In addition to Sanskrit, which is the native language of no one but is mastered and spoken by a considerable number of scholars, and Urdu, which is a special literary form of Hindi, it named the following 12 main languages: Assamese, Bengali, Gujarati, Hindi, Kannada (Kanarese), Kashmiri, Malayalam, Marathi, Oriya, Panjabi (Punjabi), Tamil, and Telugu. Of the 26 languages with over half a million speakers, this enumeration excluded (1) 4 languages spoken only in Pakistan—Lahnda, Sindhi, Pushto (Pash-to), and Baluchi (Balochi); and (2) such languages as either have less than 1.5 million speakers or, like Bihari, lack a literary culture.

The accompanying table enumerates the 22 languages of more than half a million speakers as given in the census of 1931. Owing to the rather rapid growth of the population, later figures would be much higher. Where dependable figures are available from the 1951 census, they are added in parentheses.¹ Since the Pakistan border cuts through the area of Panjabi in the west

¹ As noted in the Census of India, Paper No. 1, 1954, *Languages—1951 Census*, pp. 1-2, falsification of some returns made it impossible to give overall figures for certain major languages, such as Hindi. Moreover, a different system of tabulating languages and dialects prevented the comparison of other figures with the returns of the 1931 and earlier censuses.

and that of Bengali in the east, the figures for these two languages include many speakers in Pakistan.

MAJOR LANGUAGES OF INDIA

Language	Major area in which it is spoken	Number of speakers (millions) ¹
<i>Indo-Aryan</i>		
Kashmiri (a Dardic language)	Kashmir	1.5
Punjabi (Punjabi)	Punjab	16 ²
Rajasthani	Rajasthan	14
Pahari (including Nepali)	Himalayan slopes	2.3
Western Hindi	Uttar Pradesh	71.4
Eastern Hindi	Uttar Pradesh	7.9
Bihari	Bihar	28
Bengali	Bengal	53.5 ²
Assamese	Assam	2
Oriya	Orissa	11.2 (13.1)
Gujarati	Bombay	11 (16)
Bhili	Rajasthan, Bombay, Madhya Pradesh	2.2
Marathi	Bombay	21 (27)
<i>Dravidian</i>		
Kannada (Kanarese)	Mysore	11.2 (14.5)
Malayalam	Kerala	9.1 (13.4)
Telugu	Andhra Pradesh	26.4 (33)
Tamil	Madras	20.4 (26.5)
Gondi	...	1.8
Kurukh (Oraon)	...	1
Kandhi (Kui)	...	0.6
Tulu	...	0.6 (0.8)
<i>Munda</i>		
Kherwari	...	4

¹ 1931 census; dependable 1951 figures in parentheses.

² Includes Pakistan. While the division of Punjabi speakers between India and Pakistan is not ascertainable, there were approximately 41.2 million Bengali speakers in East Pakistan in 1951. ³ Enclave within the Indo-Aryan area in central India. ⁴ District centering around the point where the borders of Bengal, Bihar, and Orissa meet.

Most of the Indo-Aryan languages are used for literary purposes. While Bengali can claim to have produced some of the most original and valuable literature, Hindi has spread farthest across the borders of its homeland—partly as a language of administration; partly as a literary language, used by educated speakers also in daily life (it is the language of instruction at Osmania University, Hyderabad, the first institution of higher education to give up English); and partly as a popular lingua franca, the so-called bazaar Hindustani, widely understood and handled, though in an ungrammatical, simplified form, by uneducated people and Europeans.

A form of Hindi was the official language of the Mughal (Mogul) rulers of India, whose Persian-Arabic culture had a momentous effect on its vocabulary (and, through its intermediation, on that of other Indian languages). It was from the administrative centers of the Mughuls that Hindi spread. The Western Hindi of the capitals (first Agra, then Delhi) was considered as exemplary. This particular form of language, written in Persian script and deeply influenced by Persian also as to literary models, was called Hindustani (language of Hindustan—that is, India) and, more specifically, Urdu (literally, [language of] the camp [of the Mughul rulers and their army]). In reaction to this Persianized Urdu, a purer Hindi was developed as a modern literary language, written in Hindi, that is, a simplified form of Devanagari, a northern Sanskrit alphabet from which the scripts of the other Indo-Aryan languages also are derived. Since India became independent in 1947, there has been a widespread tendency to purge Hindi still further by eliminating loan words from Persian and English and to fill the gaps with loans from Sanskrit.

Among the Dravidian languages, Kannada, Telugu, Tamil, and Malayalam (which only in the 10th century branched off from Tamil) have an old and rich literature. Smaller specimens of the Munda languages are Santali, spoken east of Kherwari; and Kurku, spoken in central India.

Language Problems of India.—By the late 1950's many of the primitive tribes of the Republic of India had given up or were about to give up their own languages in favor of one of the great Indo-Aryan or Dravidian languages. Meanwhile, Sanskrit, as the learned language of educated Hindus, continued to play a significant role in enriching the vocabulary of the living languages.

The introduction of Hindi as the official language and the intended abolition of the use of English for purposes of administration and academic instruction have created serious problems. Though bilingualism, even among the less highly educated, is much more common and usual in urban India than in the West, the use of Hindi as a second language has been opposed for reasons of cultural prestige in the Dravidian south and also in Indo-Aryan districts of a peculiar national culture (for example, in Bengal). The total elimination of English would cut off India from considerable advantages in international, economic, and cultural relations. Only a small percentage of the population (estimated at 5 million persons in the late 1950's) has mastered English, but it is politically, economically, and culturally the leading group. Much of the political, scientific, and technical terminology is English and difficult to replace by native expressions. The linguistic problem has been one of the most controversial topics of debate among Indians, especially as an item of educational policy. Justified sentiments of national pride and practical exigencies are often in bitter conflict, whether the problem is being considered in terms of Hindi versus national languages or of English versus indigenous speech.

Professor of Sanskrit, Yale University.

10. LINGUISTIC SCIENCE

Linguistic science is a field in which India held a unique position in the ancient world. Its discovery by Europeans at the end of the 18th century led to the development of modern linguistic science in the 19th century.

The Grammar of Pāṇini.—Linguistic science in India practically begins and culminates in one great work: the Sanskrit grammar of Pāṇini (probably not later than 500 B.C.) of Salatura near modern Peshawar, Pakistan. It consists of eight "lessons," containing in all 3,873 rules, of which only about 50, or 1.3 per cent, are demonstrably later additions. With it are a list of roots and a table of sounds. The rules are actually definitions of technical terms, of principles followed in the formulation, and of grammatical operations. Unaccompanied by authentic explanations and examples, they are striking by their unrivaled terseness, which is achieved through highly ingenious devices.

Like other works of early Sanskrit literature, Pāṇini's grammar was designed to be committed to memory before it was explained. This accounts for the slight regard paid to systematic

arrangement, such as would be necessary in a book meant to be read and used for reference. The oral transmission did, however, keep the original wording in excellent condition; apart from the few additions, the changes it underwent consist in the omission of certain features of pronunciation that were neglected when the grammar was finally written down—for example, the old tonal and pitch accents, which had become obsolete in later Sanskrit.

Pāṇini's work is neither a school grammar, meant for teaching a language to beginners, nor an academy grammar, meant for establishing a standard of speech usage, but a theoretical explanation of the word formation of the sacred Sanskrit language. It furnishes the proof that Sanskrit bears its name, *sam-skṛta-*, used in the sense of "ritually pure," in the etymological (true) sense of the word: "put (-*skṛta-*) together (*sam-*)." The chief discovery and fundamental doctrine of Pāṇini, as it can be abstracted from his procedure, is as follows:

(1) Each complete nominal and verbal form of Sanskrit consists in principle of three elements, root, suffix, and ending, each of which fulfills certain definite functions. Root and suffix together form a nominal or verbal stem, from which another stem may be derived by a further suffix, before the ending is added. Stated in a formula:

$$\left. \begin{array}{l} \text{Root} + \text{suffix} = \text{primary stem} \\ \text{Primary stem} + \text{suffix} = \text{sec-} \\ \text{ondary stem} \\ \text{Secondary stem} + \text{suffix} = \\ \text{tertiary stem} \end{array} \right\} + \text{ending} = \text{word form.}$$

(And so on)

(2) The elements can rarely be separated by a clean cut. The suffixes, especially, reach into the preceding element by demanding, for example, a special degree of the root vowel (normal, strengthened, doubly strengthened, as in *i : e : ai*; *u : o : au*), a phenomenon now called apophony or ablaut.

(3) In certain cases the ending seems to be added to the root without a suffix, or a secondary stem to be derived from another one without a (secondary) suffix. Pāṇini posits here invisible suffixes, that is, inferrible suffix functions unaccompanied by a perceptible phoneme. The term in modern linguistics is "zero suffix."

(4) The final sound or sounds of a preceding element and the initial sound or sounds of a following element may undergo certain combinations that make the abstract forms of the elements unrecognizable. The conditions for these combinations can be stated in strict rules.

It is Pāṇini's greatest achievement that he applied his principles consistently to almost all instances where they could be applied. His work is the first example in scientific world literature of a theory's being tested empirically by an exhaustive marshaling of the facts. The accuracy and ingenuity with which he executed his functional analysis as well as the soberness of his judgment, which refrains from all forced explanations of resisting material, have created a descriptive presentation of Sanskrit word formation which is still valid in all essential points.

Influence of Pāṇini on the Development of Western Linguistics.—Until the beginning of the 19th century the model for all grammatical descriptions of Indo-European languages (which practically amounts to grammars of Latin and Greek) was the *Tekhnē grammatikē* (*Ars gram-*

matica or *Grammatical Art*) of Dionysius Thrax (fl. 2d century B.C.). Dionysius' description of Greek presupposes an analysis of the flow of speech into sentences, of sentences into words, and of words into their phonetic-acoustic units, the sounds (which were not clearly distinguished from their symbols in writing, the letters). The words were not analyzed into further functional elements. There was no explanation of word formation; the different case forms of a noun were looked upon as alterations of, or deflections or inflections from, an allegedly normal form, the nominative; all finite verb forms, as similar deflections from the first person singular. For Pāṇini, on the other hand, word formation is the central, intrinsic subject of linguistic description; all case forms (including of course the nominative) and all finite verb forms (including the first person singular) are formed from the stem by adding an ending.

Pāṇini's functional analysis of word forms became known in Europe through the first Western Sanskrit grammar (1808), by Sir Charles Wilkins. Following Pāṇini's principles, Wilkins remodeled his enigmatic expressions and his arrangement for the benefit of European scholars and gained, indeed, significant influence, chiefly through the works of Franz Bopp, who in 1816 created a scientific sensation by a monograph on the conjugational system of Sanskrit as compared with that of the Greek, Latin, Persian, and Teutonic languages. By applying Pāṇini's "*Zergliederungskunst*" (analytic art), known to him through Wilkins, to the verb forms of some of the related languages (postulated as such by Sir William Jones in 1786), Bopp was able to show that it works with them, too, and that the elements and the methods of word formation that can be obtained by abstractional observation correspond in the languages he scrutinized in a way that excludes an explanation by similarity due to chance. Besides the method of comparison, Bopp added the idea of historical development, completely foreign to Pāṇini and Indian linguistics in general, and thus became the founder of historically oriented comparative grammar.

Indian Phonetics.—Pāṇini's grammatical description is based not on the linguistic usage of written texts, but on the observed facts of a spoken language. Even before Pāṇini the texts of the older sacred literature (the Vedas) had received scholarly attention. Yet these texts, too, were studied as orally recited. Consequently, there never was in India any confusion between sounds and letters, which was current in Europe and of which the very word *grammar* (derived from Greek *gramma*, letter) is a clear symptom. Concentration on sounds as products of articulating movements led to an empirically founded classification of the sounds already known to, and presupposed by, Pāṇini.

New to Western grammarians was the seemingly simple discovery that different sounds are produced (1) at different "places of the mouth" and hence can be classified as gutturals, palatals, dentals, labials, and the like; (2) with different kinds of articulative "efforts"—occlusion, half occlusion, opening, and so on; and (3) with different "accompanying productions"—aspiration (for example, *kh* against *k*), voice (*k* against *g*), and nasalization (*ṅ* against *g*, *n* against *d*). Dionysius and his followers had nothing to say about the difference between, for example, *k* and *p*. They were satisfied with distinctions like *k*, *p*, *t*

as "smooth," and *kh, ph, th* as "rough," and with designations like that of the occlusives (stops) as mutes. The acquaintance with the empirical analysis of the production of speech sounds as practiced by the old Indian phoneticians furnished the starting point and foundation for modern phonetics, which had to add only refinements of their basic discoveries, won by still more accurate observation and a wider experience in different speech forms.

Later Developments of Linguistics in India.—Of the huge literature in Sanskrit complementary to Pāṇini's grammar, the two earliest preserved works are also the most significant. Kātyāyana's *Vārttika* ([Investigation] Pertaining to the Procedure [of Pāṇini], 3d century B.C.) and Patanjali's three-volume *Mahābhāṣya* (*Great Prose Work*, 2d century B.C.). They are devoted to the task of discussing the logical and factual correctness of Pāṇini's definitions. It is only later that actual commentaries, designed to explain Pāṇini's grammar and with the help of this explanation to settle which forms can and must be considered correct, come into existence. The oldest of these is the *Kāśikā* ([Commentary] from Varanasi [*Kāśī*], 6th century A.D.).

Of general interest for the history of linguistics are certain discussions of theoretical problems in Patanjali. Among these are the relation of speech sound and meaning (discussed also by Plato), the meaning of grammatical gender, and the difference between abstract concept and the concrete representative of a concept as named by a linguistic sign. Though full of sagacious observations and remarkable for their empirical method, these discussions had no influence on the development of modern linguistic science, partly because they remained unknown except to a very few specialists and partly because they are not free of the influence of certain dogmatic views held with respect to the nature of Sanskrit as a sacred language. The same holds good with respect to etymological procedures as developed by Yaska (later than Pāṇini, but earlier than Patanjali) or Indian lexicography (collections of homonymous and synonymous words), which often contain useful factual information, but reveal no outstanding skill in exegetic methods, nor any adequate insight into the problematics of semantics.

An attempt at comparative grammar was made in certain works on vernacular languages (Prakrit), related to Sanskrit, that study (among other subjects) the sound correspondences between Sanskrit and these vernaculars by establishing strict and comprehensive rules. (The oldest of these works is the Prakrit grammar of Vararuci, which cannot be dated accurately, but most probably is not earlier than some centuries after Christ.) The sound correspondences are taken as seriously as in modern comparative grammar, although there is no historical perspective as adopted and developed by Western scholars since the mid-19th century.

11. LITERATURE

CLASSICAL LITERATURE

Classical literature in India must be understood not as a literature of a particular period

or a particular kind, but as the literature composed in Sanskrit, the sacred language of the Brahman religion, in its different stages. By descent, Sanskrit is one of the Indo-European languages; it was imported into India in the 2d millennium B.C. by immigrants from the West who called themselves Aryans (Sanskrit *Ārya*). Its nearest relative is Old Iranian, as attested in the Avesta (the sacred texts of the Zoroastrians) and in the Old Persian cuneiform inscriptions of Darius I (r. 522–486 B.C.). Geographically, Sanskrit is a northwestern dialect, which through the medium of ritual usage and learned education spread, in the course of the 1st millennium B.C., as a kind of lingua franca throughout the Indian peninsula. Sociologically, it represents the standard of educated speech set by the priestly caste, the Brahmins. It is used for literary purposes first in priestly poetry, then in all kinds of other compositions of a ritual, scientific, and, ultimately, of an entertaining character. Chronologically, it may be divided into Vedic, the language of the earliest literary monuments; early classical, the language of early scientific prose; and late classical and postclassical, the language used in varying grades of purity in the epics and the later, highly stylized poetry and prose (as such, it has continued to exist, in an ever-decreasing degree of importance, into the 20th century).

Sanskrit literature is classic in the sense that it actually played the role of a model for other old Indian literatures as they developed in dialects related to Sanskrit and in such unrelated languages as Tamil. It is classic also in the sense that it has a claim to be ranked among the great world literatures with regard to scope and variety of the subject matter, accuracy and depth of thought, formal strictness, and polish of expression. As such, it is of intrinsic interest as one of the values of man's heritage, embodied in ideas and forms created and preserved by literary art. Like all human values, this value is relative, and an attempt to appreciate it involves giving up the notion that Western standards of esthetic measurement are absolute and strictly objective. The chief interest of Sanskrit literature for Western man certainly lies in its being a rich source for the history of religion, philosophy, and scientific thinking.

For practical purposes we include in this survey two branches of old Indian literature not in Sanskrit, but in related vernacular speech forms. Prakrit literature is in part directly connected with Sanskrit, and in part constitutes the sacred and scholastic literature of the Jains. Pali literature is exclusively Buddhist.

Vedas.—*Rig Veda.*—*Origin and Tradition:* The oldest document of Sanskrit literature is a collection (*samhitā*; Sanskrit *saṃhitā*) of 1,028 hymns called the Rig Veda (*R̥gveda*; Knowledge of Verses), the work of various poets of the 2d millennium B.C. There is no doubt that these hymns were composed without the help of the script and were for many centuries handed down exclusively by word of mouth. This oral tradition left the text free of any significant corruptions, as can be demonstrated by linguistic, exegetic, and metrical investigations, which vindicate the correctness of the traditional text (except for certain accurately definable modernizations concerning pronunciation and enunciation).

Contents: The hymns of the Rig Veda are celebrations of various gods, meant in the main for recitation at the solemn fire ritual. The nature

of this poetry can be understood only when it is related to the nature of the gods it praises and to its prehistoric origins. Some chief figures among these gods are Agni, Soma, Indra, and the Adityas.

Agni is the personification of fire (*agni*, related etymologically to the Latin *ignis*, fire) regarded in its different aspects—for example, as devastating forest fire; more often, as the household fire that presides over and protects the family; as the fire used in the cremation of the dead; and chiefly, as the ritual fire on the sacrificial ground that brings the sacrificial gifts to the gods, or around which the gods are supposed to gather as the guests of man, who offers them food and drink and honors and entertains them by the recitation of poetry. Agni himself is often described as the divine poet and priest, whose poetry is in the crackling of his flames.

Soma (Avestic Haoma) is the personification of an exhilarating drink (soma; literally, pressing) won from the stalks of a particular plant. He helps the poet in his ecstatic concentration and supports other gods in their heroic feats. His descent from heaven and his return to it after he has been ritually purified are the subject of a difficult mysticism, a complicated ritual, and some colorful legends.

Indra (in the Avesta the name of a demon) is the god of victory. His originally rather abstract figure is embellished by lending it the features of a dragon-killing hero and ascribing to it the primordial feats of setting free the water, the light, and the milk-giving cattle through an initial victory that creates the conditions for life.

The Adityas are a group of gods who personify ethical concepts: Varuna (True Speech), Mitra (Contract, Treaty), Aryaman (Hospitality), Bhaga ([Fair] Share), and so on. Like Soma and Indra, they have some exact correspondences in the Avesta, where we find the gods Mithra, Airyaman, and Baga. Consequently they must be explained as inheritances from the time when the Aryans (the Indo-European-speaking Indians and Iranians) still used a common speech form and constituted a common national community of some kind. Varuna, Mitra, and Aryaman center around the (neutral) concept *rita* (*ṛta*, truth), conceived as immanent in all ethical behavior and also as a miraculous creative power through which the universe was established as a system of interrelated entities and dependable happenings (sunrise, rain, alternation of day and night), guaranteed by divine vows (*vrata*), to which corresponds man's vow to abide by truth and to offer sacrifices. The sacrifice is a re-enactment of this primordial covenant between man and gods.

The hymns themselves are conceived as formulations (brahman) of esoteric revealed truths concerning the divine powers and their characters and achievements. As formulations of esoteric truth, they are loaded with its miraculous power. The Rig Vedic poetry is, then, quite a unique kind of literature, based on a combination of an imaginative polytheism, an ethical interpretation of life, and the conviction of the spell-like working of truth formulated in speech.

Form: In contradistinction to the *Homeric Hymns*, which are epic in character, the hymns of the Rig Veda are lyric and dithyrambic. A god's feat is not recounted but is celebrated in a gorgeous, but often sketchy, even abrupt style. The poets are fond of hidden implications, sudden

interruptions, and striking images, sometimes striving after artificial ambiguity and mystic obscurity. Only occasionally is a legend treated in a more coherent manner, but even then the style is balladic rather than epic, the theme being developed in a dramatic dialogue full of allusive references from which the frame of the story must be reconstructed.

It is obvious that this characteristic, highly developed style must be the result of a long poetic practice that reaches back far into prehistoric times. The nearest ancestor of Rig Vedic poetry, a proto-Indo-Iranian poetry, can be reconstructed in abstract outline by a comparison of the oldest Iranian sacred poetry, which shows a great number of close correspondences in subject matter, in diction, and in metrical patterns. Its further removed ancestor, a proto-Indo-European poetry, can be dimly recognized by a comparison of old Greek lyric and epic poetry, which also shows certain definite correspondences in diction and metrics. The most important figures of Vedic and Iranian religion, however, cannot be traced back to proto-Indo-European times.

Later Vedic Literature.—The *Other Collections*: The hymns of the Rig Veda were recited at the fire sacrifice by a particular priest, the *hotṛ*- (Old Iranian *zotar*, reciter). At certain occasions of this sacrifice hymns were sung on a melody by the *udgātṛ*- (singer), for whose study all the Rig Vedic hymns used in this way were collected in the *Sāma Veda* (Knowledge of Melodies). On other occasions a third priest, the *adhvaryu*-, whose chief function was the execution of the ritual acts themselves, had either to recite single verses or to mutter prose formulas. This material is collected in the *Yajur Veda* (Knowledge of the Sacrificial Prayers), preserved in different school texts (the main divisions are the Black and the White *Yajur Veda*). In part it repeats verses from the Rig Veda, and in part it adds verses of its own that are closely patterned on Rig Vedic models. There are also a number of prose formulas that have some close correspondences in the Avesta, which proves the prehistoric age of this genre of composition.

The latest of these *samhitā*, the *Atharva Veda*, is the only one that has no specific relation to the fire sacrifice. In contrast to the *Yajur Veda*, it contains chiefly hymns, and these are in style and diction obviously imitative of the elaborate poetic art displayed in the Rig Veda. They are meant to accompany magic practices as used outside of solemn rites: Actually they are charms for giving effectiveness to healing plants, relieving the pains of labor, endowing an amulet with power, and so on. As to content, they have to be ranked with spells as we know them from all over the world; as to form, they are solemn poetry. This peculiar combination lends the *Atharva Veda* its particular interest for the study of magic religion and for that of literary forms.

Brāhmanas and Upanishads: The oldest example of prose composition (prose sentences built into a unified artistic whole) is furnished by the texts called *Brāhmanas* (works containing formulations, brahman, of the truth). These texts, the oldest of which form part of the Black *Yajur Veda* collections, are concerned with stating and explaining the esoteric, mystic significance of single ritual acts. Partly narrative and partly argumentative, they are couched in a strict and terse language, which is of an impressive directness, accuracy, and stylistic consistency—the

forerunner of later scientific prose.

Considerably later than the Rig Veda, the Brāhmaṇas are earlier than the earliest (prose) Upanishads (*Upaniṣad*; literally, Worshipful Approaches) that speculate and argue in a manner similar to that of the Brāhmaṇas (not, however, on ritual acts, but on the essence of nature and the universe). They have charmed Western philosophers by their monistic attitude, which is essentially atheistic and materialistic. It is more akin to Greek pre-Socratic philosophy than to Plato's idealistic and moralistic interpretation of the world. If it is Plato's aim to improve man by making him wiser, the purpose of the Upanishads is to offer truth as a magic weapon to obtain practical ends, the highest of these being salvation. Their basic outlook is best characterized as magic philosophy or philosophical magic. The argumentation of the Upanishads is more assertive than persuasive. It is ruthless in demolishing confidence in appearances and reducing them to their essential "beingness." Besides much deductive speculation, it offers remarkable instances of reasoning by induction and experimentation.

The oldest Upanishads may be said to contain in germ most of the basic issues of later Indian philosophy, including the dogma of transmigration (foreign to the older Vedic tradition); the doctrine of the partition of matter into fire, water, and earth, which by combining in different ways constitute all that can be perceived by the senses; and the postulate of the self (atman; Sanskrit *ātman*) as the unqualifiable, imperishable "reality's reality," which is only temporarily imprisoned in finite bodies. Later these ideas are partly developed and amalgamated with theistic beliefs, as in the *Bhagavad Gītā*; partly attacked and refuted, as in Buddhist philosophy; and partly reinterpreted and fitted into new systems, as in the philosophy of Vedānta, represented in its two classic branches by Śaṅkara (Śaṅkara, fl. about 800 A.D.) and Rāmānuja (fl. probably 12th century).

Scientific Literature.—Scientific literature in the proper sense begins with the old Sūtras, which describe the complicated rites of the Vedic fire sacrifice. The name Sūtra (literally, means of sewing, thread) derives most probably from these descriptions aiming at "sewing together"—that is, arranging according to their sequence and coordinating—the single sacrificial acts and verses into a unified body. Characteristic of all the Sūtras is their relentless striving after brevity of expression and their purely factual point of view, which leaves no room for any attempt at explanation.

Factual description as a means of making clear and proving a theory is found first in the grammar of Pāṇini (fl. probably not later than 500 B.C.), which describes the processes of the word formation of Sanskrit in the light of the assumption that words consist of smaller functional elements (root, suffix, ending) and that they are put together (*sam-skṛta*) according to strictly definable methods.

Descriptions of a less rigorous character, partly in verse, are other works dedicated to the simpler customs of the home ritual and private life (*Gṛhyasūtra*) and of traditional customs sanctioned by the Brahmins in a wider sense (*Dharmasūtra*). Occasionally they approach the character of versified law codes, of which the most famous is the *Manu Smṛti* (*Tradition of Manu*).

In later times, from about the 3d century B.C.,

scientific works are preferably composed as discussions of and commentaries to older authoritative texts. The classic model for this type of scholastic investigation is Patanjali's *Mahābhāshya* (*Great Prose Work*, 2d century B.C.) on Pāṇini's grammar. It shows distinctly how this kind of composition came into existence: it is a literary stylization of conversations between scholars examining exegetic, logical, and material difficulties found in earlier works by raising points of objection and seeking answers that would remove them. As Patanjali himself tells us, Sanskrit was then still a spoken language in part of northern India. This is borne out by the freshness of his style, which successfully imitates the manner of spoken speech by its short, often elliptical sentences and idiomatic phrases. Later, when Sanskrit had become a pure school language, the style of the commentaries is increasingly abstract and abstruse.

A similar line was followed by the development of philosophical literature, which was earlier composed in Sūtra style and later in commentary style. It is by nature logical, epistemological, and metaphysical, its epistemological and logical aspects coming more and more to the fore, and in the end absorbing almost completely all other interest. Important for the comparative study of philosophy are the Indian system of topics (*padārtha*), corresponding to a certain degree to Aristotle's categories; the Indian atomistics; and the Indian investigation of knowledge by inference (*anumāna*), corresponding to the syllogism of Western formal logic.

The recognized triad of ways of life—according to dharma (pious custom), artha (practical purpose), and kama (Sanskrit *kāma*; sensual desire)—led to the complementation of the existing dharma literature by works teaching the artha (the outstanding example is the *Kauṭīliya Arthaśāstra*, the core of which is of the late 4th century B.C.) and the kama (the outstanding example is Vātsyāyana's *Kāmasūtra*, ill reputed but of high ethnological and folkloristic interest).

Entertaining Literature.—Epic Poetry.—Storytelling reaches the level of literature when it becomes an art which follows certain patterns of form and style. In India as elsewhere, one of the basic kinds of narrative literature is the epic poem, whose most general characteristics are its metrical form and its leisurely style, which unfolds the story with constant attention to detail and frequent digressions. The oldest and most important Indian epic poems are the *Mahābhārata* (*Great Tale of the Descendants of Bharata*) and the *Rāmāyana* (*Life of Rāma*). Both are composed in a Sanskrit that here shows some popular influence, particularly in the *Mahābhārata*; both are composed in meters that can be derived from Rig Vedic ones; and both are full of religious themes and are regarded, with increasing veneration, as sacred works. The *Mahābhārata* purports to be a story told by a sage of old at a sacrifice. The link to Vedic tradition is thus apparent. Obviously it is just these Brahmanical features (language, meter, ritual background) that have raised old folk tales and legends to the rank of literature thought worthy to be handed down in this particular form to posterity.

The *Mahābhārata*, though younger than Vedic literature, is not later in origin than the second half of the 1st millennium B.C., though it may contain some more recent additions. It is a gigantic work, comprising in its present form about

100,000 verses. Its main theme is the great war between two sets of hostile cousins, the Kurus or Kauravas and the Pāṇḍus or Pāṇḍavas, which culminates in a huge battle in the plains north of Delhi. The course of events is frequently interrupted by inserted tales, often of considerable length, related by figures playing a role in another story (the technique of stories within a story). These episodes are of a remarkable variety and furnish much of the basic material of later narrative literature. The best known is the conversation of the Pāṇḍu hero Arjuna with his charioteer Krishna (*Kṛṣṇa*) on the duties of a warrior king, held at the beginning of the battle. It is not only full of ethical reflections, but contains the chief tenets of Hindu faith as connected with the worship of Vishnu: Krishna reveals himself as one of the incarnations of the god, assumed by him to help mankind in time of distress. This is the *Bhagavad Gītā* (*Secret Wisdom Sung by the Lord* [Krishna]), one of the main sources of edification and inspiration for modern Hindus (it was Mohandas K. Gandhi's favorite work).

The *Rāmāyana*, which is shorter and more polished, and which keeps more consistently to its main subject, relates the heroic adventures of the prince and later king, Rāma, victor over the demon king Rāvaṇa, who had abducted his wife, Sītā. In his conquest of Rāvaṇa's island capital, Lanka (later identified with Ceylon), Rāma was helped by an army of monkeys, whose leader, Hanumān, became a popular figure of the Hindu pantheon. Like Krishna in the *Mahābhārata*, Rāma is considered to be an incarnation of the god Vishnu, while Sītā is venerated as the prototype of noble Indian womanhood.

Later epics in Sanskrit, the Purāṇas (Old Stories), take up and develop certain themes of the older epics, especially the Krishna legend; they have become the chief source of modern Hindu legend and mythology. The *Rāmāyana* was revived and given its finally valid form by the poet Tulsī Dās (1532-1623) in his *Rām-carit-mānas* (*Wonderful Lake of the Life of Rāma*), composed in Hindi.

Learned Poetry (Kāvya) and Prose.—The narrative poetry of the *Rāmāyana* is, in style and manner, the model of later artistic poetry, which tries to emulate it and certainly surpasses it in formal polish. In general, it can be maintained that the later a poem is, the less original are its contents, the more elaborate and accomplished its external qualities. The learned character of this poetry, which is sociologically a court poetry, would be evident even if we did not have certain works that, in the Sūtra style, lay down rigorous rules for poetic composition.

The oldest well-known poets of this kind are Aśvaghosha (fl. about 100 A.D.), a Buddhist who in his epic poem *Buddhacarita* (*Life of the Buddha*) endeavored to give the Buddhists a Sanskrit epic that could replace for them the *Rāmāyana*; and Kālidāsa (fl. about 5th century A.D.), the universally recognized classic of this style. Kālidāsa's epics are elaborate versions of tales taken from the old epics and the Purāṇas: *Raghuvamśa* (*Lineage of Raghu*) tells the legendary history of the ancestors and descendants of Rāma and the Rāma story itself; *Kumārāsambhava* (*Origin of the God Kumāra*) relates the happenings that led to the wedding of the god Shiva (*Śiva*) and Pārvatī, the daughter of the Himalaya. The lyric elements in these poems are so strong as almost to cover the epic fundament. Kālidāsa's

imaginative description of nature, which appears in a pure form in his most famous work, *Meghadūta* (*The Cloud Messenger*), is unparalleled in classic Hellenistic and preromantic European poetry. Actual observation and a genuine pleasure in nature's beauty find here a romantic, sentimental, and idealizing expression that enchanted European poets like Johann Wolfgang von Goethe.

An equally great impression was made by Kālidāsa's play *Sakuntalā*, the first work of Sanskrit literature to be translated into a European language (by Sir William Jones, in 1789). Even here the treatment is prevalently lyrical. The theme is again taken from the epics (*Mahābhārata*), as is that of many other Sanskrit plays. Other types of plays deal with courtly love stories. Only one play, *Mṛcchakatika* (*The Little Clay Cart*), which in its original form is older than Kālidāsa, has a realistic contemporaneous background and presents an interesting picture of life in a medieval Indian city.

From a still later time we have some prose novels, similarly composed in a highly artificial style meant to appeal to learned palates. The most original is Daṇḍin's *Daśakumāracarita* (*Adventures of the Ten Princes*, 6th or 7th century A.D.), which can be compared to *The Little Clay Cart* in its vivid description of contemporary life. Notwithstanding its sophisticated and difficult language, it can be enjoyed as a picaresque novel.

Sanskrit sententious poetry is perhaps more to Western esthetic taste; this consists of short verses in a comparatively easy style, dealing with themes of ethical and worldly wisdom, and also with the joys and griefs of love. The chief representative is Bhartṛhari (Bhartṛhari, fl. probably 7th century A.D.).

The writing of history as a sober and serious attempt at relating past or contemporaneous happenings is unknown in India. The few lyric-epic poems or prose compositions that deal with royal history are more often than not on the other side of the border line that separates fact from fiction. Worth mentioning in this connection are some panegyric inscriptions (*prāśasti*) like that on a stone pillar in Allahabad (345 A.D.) celebrating in *kāvya* style the war feats and the learned accomplishments of King Samudragupta (r. about 330-375/380 A.D.). Kalhana's *Rājataranginī* (*River of Kings*, 12th century A.D.), a poetic chronicle of Kashmir, is comparatively sober and helpful for historians.

The great mass of Sanskrit fable literature is of a pseudolearned character. Its sources are obviously simple popular tales, whose heroes are chiefly humanized animals. The language of the Sanskrit fables is strongly influenced by popular speech, though it tries to imitate *kāvya* style. Ostensibly the fables are told and arranged to teach worldly wisdom, especially of a political nature, and are considered a kind of *Arthaśāstra*. They have found their way into many countries outside India. The chief representative of the genre is the *Panchatantra* (Sanskrit *Pañcatantra*).

Vernacular Literature.—Prakrit Literature.—Prakrit language as a vehicle of literary expression is found in Sanskrit literature proper in the plays. Here different persons speak in different dialects, the geographical distinctions of the dialects being treated (in a manner not quite true to life) as distinctions of social level. This rather strange practice seems to point to the origin of Sanskrit drama as a shadow play, such as is still found in parts of southern India and

flourishes in Java. In a shadow play it was of course necessary to find a means of distinguishing clearly between the speeches of the different actors, which were actually spoken by one person, the *sūtradhāra* (holder of threads), as the "theater director" is still called in Sanskrit.

Learned lyric-epic poems in Prakrit imitate exactly Sanskrit prototypes, as does Prakrit sententious and lyric poetry. More independent of Sanskrit models is the literature of the Jain religion, composed in two different old vernaculars, corresponding to its two sects, and later in Apabhramsa, a more modern form of Prakrit that forms an intermediate stage to the modern dialects. The Jain literature is especially remarkable as a treasure house of tales. *The Arabian Nights* contains quite a few motifs that may be of Indian (Jain) origin and shows a striking similarity in its elaborate use of the technique of stories within a story, as perfected in Jain narrative literature.

Buddhist Literature.—The canonical records of southern (Hīnayāna) Buddhism, the Pali Tipiṭaka (Three Baskets), consisting of the Vinaya Piṭaka (Basket of Religious Training), Sutta Piṭaka (Basket of Teachings), and Abhidhamma Piṭaka (Basket of Things Relating to the Doctrine), are composed in a stylized vernacular. Actually a mixture of several vernaculars, and possibly a lingua franca for north Indian trade, this is basically a northeastern dialect (Ardhamagadhi) of a much more archaic form than the literary Prakrits. The Tipiṭaka, which is the most important text of Buddhist literature, contains the life story of the Buddha and a number of his sayings, more or less faithfully handed down by oral tradition. It is a collection of chronologically different layers; the oldest consists of verses in a particularly archaic language, connected by prose narrative and commented upon at a later time. Aside from its interest for the history of Indian philosophy and religion, the oldest Buddhist literature is interesting for its store of legends and tales, partly original and partly corresponding to the Sanskrit epic tradition, with which it may have culled from the same popular sources, and to Sanskrit sententious poetry. The *Jātakas*, stories dealing with former births of the Buddha that form part of the Sutta Piṭaka, offer the earliest instances of Indian fable literature.

Since the time of Aśvaghosha there have been numerous attempts at providing Buddhism with a literature in Sanskrit. These are characteristic of the northern (Mahāyāna) school, which was exported to Tibet and China. Here there exist numerous translations from Buddhist Sanskrit that complement our knowledge of texts preserved in Sanskrit. The Sanskrit of the northern Buddhists (with the exception of Aśvaghosha) is heavily mixed with elements from Pali and other vernaculars, and the question has been raised of whether it was originally meant to be Sanskrit at all or whether it is in fact rather a particular, superficially Sanskritized vernacular. The texts in this Buddhist hybrid Sanskrit are of great value for the study of the history of northern Buddhism as it was developed by its monks. There is a growing tendency to adorn the originally simple and touching story of the Buddha by the introduction of miracles and to replace the older plain narrative prose by a style strongly redolent of Sanskrit court poetry and prose.

MODERN INDO-ARYAN LITERATURE

The modern literatures of India serve to record the interacting social, political, historical, economic, and intellectual forces which gave impetus and direction to the development of the country. Their evolution demonstrates the striking changes brought about by contact with the West. (For the earlier literature in these languages, see separate articles on them.)

Introduction of Western Influences.—Several events stimulated the dormant Indo-Aryan literatures in the early 19th century. Among them were the establishment in 1800 of the College of Fort William in Calcutta; the introduction of printing, accompanied by the standardization of orthography and fonts, and the more extensive use of punctuation; and the decision of the government of Bengal in 1835 to make English the medium of instruction in the schools for lower-echelon government officials.

The College of Fort William was established to train British civil servants in the languages, history, law, and customs of the country. Since their administrative duties required them to be conversant with the colloquial dialects, a portion of the college's curriculum was devoted to this study. This official recognition eventually influenced the progressive element among educated Indian groups, which was curious to explore the avenues opened by the new Western ideas, to cultivate the colloquial languages for literary purposes. Added impetus was given by the printing press, which made possible the development of a large reading public, in sharp contrast to the limited audiences that had hitherto been reached by literary works transmitted either through manuscripts or through readings by authors or by *kathaks* (professional reciters).

Although some Indians were acquainted with French at the beginning of the 19th century, it was the introduction of English education which made European knowledge available to India and revealed new literary forms—the novel, the novellette, the short story, the essay, the newspaper article, biography, literary criticism, and, in dramaturgy, the tragedy and the one-act play—to whose exploration the young writer eagerly applied himself. Even after the achievement of independence in 1947, English continued to play an important role in Indian life.

Development of New Themes.—Prior to the 19th century renaissance verse composition was the principal literary activity in India. The countless treatises prescribing methods of versification and the selection and treatment of the preponderantly religious or philosophical themes underscored the severe restrictions placed upon the author. Innovation was further discouraged by the conventions set by the classical literatures—Sanskrit for the Hindus and Persian and Arabic for the Muslims. The literary languages which evolved, with their vocabulary and syntactic constructions borrowed directly from the classical literatures, were actually special di-

alects, distinct from those employed in everyday communication. An example of this is the contrast between the *sādhū bhāṣā* (literary language) and the *cholī bhāṣā* (colloquial language) in Bengal.

The new movements broke away from tradition. Poets turned to an alien literature, English, for their models and inspiration, and they experimented with new meters and attempted to revive older indigenous verse forms. Among the imports from the West were blank verse and the sonnet. The epic was refashioned, with emphasis on the narrative aspect instead of the traditional religious aspect, and the lyric, which hitherto had existed only as part of a larger composition, was cultivated as a separate entity. A striking feature of the new age was the emergence of prose, which previously had been confined mainly to philosophical treatises or to such narrative expositions as the fable or fairy tale and the romance. While poetry was not entirely free of the hobbles of tradition, prose lent itself readily to new influences, cultivating the colloquial rather than the literary languages.

The new themes dramatized the changes in attitudes induced by Western influences. Secular and popular subjects replaced the religious and esoteric. The writer's attention was focused on man and his earth-bound trials and tribulations instead of the overworked exploits of gods and mythic heroes with their stereotyped treatment, as prescribed by the antique standards. The novelist, with European works as models, constructed his plots around the realities of daily life and the problems which perplex the individual in a society in transition. A favorite topic was the need for social reform, specific attention being given to the lot of men caught in the toils of the caste system and to the disabilities suffered by women—illiteracy, early marriage, and enforced widowhood. In time the historical novel and the mystery novel each found a loyal public. Caught up in the nascent nationalist movement, writers turned to India's past for inspiration, fashioning the glorious exploits of former times into an expression of the awakened aspirations for nationhood.

Modern Literary Forms.—By the 1920's the short story had surpassed the novel in popularity in India. This literary form, devised to express a single mood or experience, is distinctly a European import, unrelated to the indigenous folk tale. It has been handled in various ways. Some writers have concentrated on the description of events. Others, like Prem Chand (1880–1936), have turned to characterization. Prem Chand was the first to choose for his dramatic personae representatives of social classes other than the elite. His pages bewail the plight of the hapless peasant and the frustration of the woman powerless to cope with adversity. Still others, experimenting with socialist theories, have directed their words to the very persons on whom their characters are modeled in order to guide and instruct them in the improvement of their condition. Meanwhile, criticism continues to be leveled at writers who employ themes considered foreign to Indian social patterns, such as the love marriage and psychological problems created by a preoccupation with sex.

Several reasons have been suggested to explain the popularity of the short story over the novel. One is the far longer time required for the production of the novel. In India, where

the writer can rarely depend on his pen alone for his livelihood, this is a significant factor. Moreover, publishers willing to take the risk of printing novels are few as compared with the magazines devoted solely to the short story.

Mention must also be made of the work of journalists and editors, especially the latter, around several of whom important schools of writers developed. In literary criticism, Indians adopted English standards to the point of quoting Western critical works for authority and of resorting to European writing for examples of the literary craft.

Modern tragedy, though lacking the popular appeal of comedy, made its way upon the Indian stage in the 20th century. Indian dramaturgy had had no counterpart to the tragedy of the West, in which the development of the plot is attendant upon the free acts of the protagonists. In the traditional Indian drama the hero and heroine, after overcoming innumerable obstacles, are joyously reunited. The wicked man is foredoomed, for, according to Hindu theory, a man's acts and present existence are strictly determined by karma, the consequences of acts performed by him in an interminable series of previous births.

Until the attainment of independence in 1947 the struggle for freedom monopolized the Indian writer's attention and was his chief source of inspiration. The new nation was slow to find literary expression, however, for with the end of foreign rule as a focus of attention the writer was caught up in the pull of diverse forces, significant among them the subnationalist tendencies reflected in the demand for linguistic states. Acutely aware of the need for communication among writers, one Indian critic suggested that arrangements be made available for the translation of works in the various languages. Hindi, the national language, was proposed for this function, but did not receive wholehearted acceptance.

Bengali Literature.—It is generally acknowledged that Bengal sparked the Indian literary movements of the 19th century. Rām Mohun Rai (Rām Mohan Roy, 1772/1774–1833), the great reformer, pioneered in literary prose. *Digdarshan*, the first vernacular journal, appeared in 1818, and it was followed in 1831 by *Sambad Prabhākara*, a literary review founded by Ishwarchandra Gupta (1806–1858), the father of Bengali journalism. Many writers of the period began their careers on Gupta's newspapers.

Blank verse, a significant import from the West, was introduced in the epic *Tilottama*, by Michael Madhu Sudan Dutt (1824–1873), who also experimented with the sonnet form and wrote the first comedy and the first tragedy in Bengali. Bankim Chandra Chatterji (1838–1894), who with his social and historical novels inaugurated modern Indian fiction, holds uncontested claim to the title of Bengal's greatest novelist.

In 1913, Bengali literature received international recognition by the award of the Nobel Prize for literature to Rabindranath Tagore (1861–1941), India's greatest man of letters. Poetry, drama, fiction, essays, criticism—there was no form of literature that his genius had not mastered.

The first financially successful writer was Sarat Chandra Chatterjee (1876–1938), whose loyal readers made it possible for him to depend on his pen alone for his livelihood. Among later writers are Buddhadeva Bose (1908–), poet,

essayist, short story writer, and critic; and Bibhuti Bhushan Banerjee (1896-1950), novelist and short story writer, whose *Pather Panchai* (*Song of the Road*) won international acclaim when it was translated to the motion picture screen. The novels and short stories of Annada Sankar Ray (1904-) are distinguished by their subtle characterization, while Tarasankar Bandyopadhyay (1900-) owes his great popularity to his studies of regional life.

Hindi Literature.—The initial phase of modern Hindi literature was dominated by Bharatendu Harishchandra (1850-1883) and by Mahavirprasad Dwivedi (1868-1938), who fostered many fledgling writers in his journal *Saraswati*. Dwivedi also molded standard literary Hindi into a tool worthy of the genius of Prem Chand, who first attracted recognition by his works in Urdu.

The period between World Wars I and II saw two significant movements in Hindi. The first, known as the *châyāvāda* (romanticism), was characterized by a revolt against formalism and didacticism. It concentrated mostly on poetry, and its leading spokesmen were Nirala (pseudonym of Suryakant Tripathi, 1896-) and Sumitranandan (Sumitranandan) Pant (1900-). The second was *pragativāda* (progressivism). It developed as a reaction to the romanticism of the *châyāvāda* and, influenced by Marxism, concerned itself with the realities of daily life and the plight of the downtrodden segments of society. It had among its adherents Yashpal (1904-) and Nagarjun (1911-).

To the post-World War II period of the *mayi kavita* (new poetry) belongs Ajñeya (Agyeya, 1911-), who represents the *prayogavāda* (experimentalism). Later fiction writers directed their attention to the life and folkways of their particular regions.

See also **HINDUSTANI LANGUAGE AND LITERATURE.**

Urdu Literature.—The moving force behind the revival of Urdu was Sir Sayyid Ahmad Khān (1817-1898), the founder of the Aligarh movement, which sought to harmonize Islamic culture with Western learning. Asad Allah Khān (called Mirza Ghālīb, 1796-1869), Muhammad Husain Azad (d. 1910), Altāf Husain Hālī (1837-1914), and Muhammad Iqbal (1876-1938) are the brightest luminaries of Urdu poetry, the last outshining all the others. Prem Chand, mentioned above for his work in Hindi, is considered to have given the Urdu short story its form, and his *Maidan-e-Amai* (*The Field of Hope*) inaugurated the modern Urdu novel. Between his death in 1936 and the creation of the two nations of Pakistan and India in 1947 many writers received recognition for their work in the short story and the novel, among them Saadat Hasan Manto and Krishna Chandra. The tragedy of partition was reflected in writing on both sides of the new boundaries.

Gujarati Literature.—The chief figures of the first period of modern Gujarati literature (1850-1885) are Kavi Dalpatram Dahyabhai (1820-1898), who served as a link with the traditional literature; and Narmadshankar (1833-1886), the architect of modern Gujarati. The interest in the new literature was reflected in the number of literary societies that were formed at this time, among them the Gujarat Vernacular Society and the Forbes Gujarati Sabha, both of which were still active in the mid-20th century.

The next period (1885-1914) was distinguished

by the novel *Sarasvatichandra*, the first great classic of Gujarati fiction, by Govardhanram Tripathi (1855-1907), from whose characters Gujarati readers drew inspiration for many years. His contemporaries were Manilal Nabhubhai Dvivedi (1858-1898), essayist and critic; and the poets Narsimhrao Divatia (b. 1839) and Kavi Nanaial Dalpatram (b. 1877). Kaniyalal M. Munshi (1887-), politician, lawyer, and littérateur, who bridges this and the following period, explored the various literary forms from the essay and the social drama to autobiography. He attained the greatest popularity with his historical novels.

The philosophical and political writings of Mohandas K. Gandhi (1869-1948), the simplicity of whose prose style wielded a strong influence on the language, dominated the next phase (1914-1948). Novelists who have made important contributions to the new India are Darshak (pseudonym of Manubhai Pancholi) and Pammalel N. Patel (1912-), the latter esteemed for his rural tableaux. Among later short story writers are Gulabdas H. Broker (1909-), Jayanti G. Dalal (1909-), and Chunilal K. Madia (1922-). Translations from foreign and other Indian authors are numerous.

Marathi Literature.—The year 1885, which saw the publication of the first poem of Keshavsut (pseudonym of Krishnaji Keshav Damle, 1866-1905) and the first novel of Hari Narayan Apté (1864-1919), marks the beginning of modern Marathi. Effective prose styles were developed by Gopal Ganesh Agarkar (1856-1895), on the one hand, and Lokmanya Bal Gangadhar Tilak (1856-1920) and Vishnushastri Chiplunkar (1850-1882), on the other, in the course of their spirited debates over social and political reform, which appeared in the newspapers *Sudharak*, edited by Agarkar, and *Kesari* and *Maratha*, under the direction of the two latter.

The period 1920-1945 was characterized by contrasting schools of poetry—the romantic, led by Bhaskar Ramchandra Tambe (1874-1941), and the realistic of the *ravikiran mandal*. Novelists of this period include Vaman M. Joshi (1882-1943), Shridar Venkatesh Ketkar (1884-1937), Vishnu Sakharām Khandekar (1898-), and Narayan Sitaram Phadke. The short stories of Phadke and Khandekar, who continued their activity in the next period, set a model for the form, in reaction to whose artificiality Y. G. Joshi fashioned his sketches of home life.

After World War II, Marathi writing was oriented toward the examination of the realities of life and toward experimentation with the use of the living language. Gangadhar Gadgil, Arvind Gokhale, Y. D. Bhavé, and Vyankatesh Madgulkar were active in the short story; and S. N. Pendse in the novel.

Other Indo-Aryan Literatures.—The many literary circles which have sprung up since independence and the number of works which have been published emphasize the growing activity in the other Indo-Aryan languages (Assamese, Kashmiri, Oriya, Panjabi), which hitherto had lagged far behind the pace set by the literatures discussed above.

ERNEST BENDER,
Research Associate Professor of Modern Indo-Aryan Languages and Literatures, University of Pennsylvania.

DRAVIDIAN LITERATURE

Of the 17 or 18 languages classed as belonging to the Dravidian group, only four—Malayalam, Kannada (Kanarese), Tamil, and Telugu—have been extensively cultivated as literary media. The literatures in these languages, like the other regional literatures of India, are to a great extent derivative in nature, being heavily indebted to Sanskrit for both form and content. The earliest works in all four of these south Indian languages employ vocabularies that contain many words borrowed from Sanskrit, while their motifs can also in large measure be traced to Sanskrit sources, in particular to the great epics, the *Mahābhārata* and the *Rāmāyana*.

While the antiquity of the Dravidian literatures is uncertain, many scholars regard Tamil as having the longest and most nearly independent literary tradition. Malayalam, a comparatively late offshoot of Tamil that developed only after the beginning of literary activity in south India, has the weakest claim to seniority. In their modern phases all four literatures show the steadily increasing effects of contact with Western, particularly English, literature. Among developments of the 20th century are the exploitation of political nationalism as a literary theme and the growth of such literary forms as the drama, the novel, and the short story. Moreover, whereas before the modern period literary works were almost always written in a dialect and style far removed from the ordinary speech of the people, the language of much of the literature written in the 20th century is sufficiently close to the spoken variety to be intelligible to the ordinary reader. At the same time, there has been an increase in the literacy rate and in the number of newspapers and magazines written in south Indian languages.

Tamil Literature.—According to a traditional account, Tamil literature originated as far back as 10,000 B.C., when the first of three successive *sangams* (literary guilds) is said to have been established to foster the production of literary works and to judge their artistic merit. Of the three traditional *sangams*, only the third has a reasonable claim to historical reality, the consensus of informed opinion placing it generally in the first centuries of the Christian era. Many of the classical works of Tamil literature are said to have been written during the period of the third *sangam*.

The earliest known works in Tamil are collections of lyrical and narrative poetry. The lyrical anthologies are eight in number (in Tamil, *Eṭṭutokai*). Most of them deal with love themes, a few describe the virtues incumbent on a good king, and still others are songs in praise of particular men and gods. Another anthology, the *Pattuppāṭṭu* (*Ten Songs*), is more narrative in content. Both the *Eṭṭutokai* and the *Pattuppāṭṭu* are invaluable for the information they provide on the religion, customs, and political and social conditions prevailing at the time of their composition.

In Tamil literature, as in other Indian literatures, works on grammar occupy an honored position. The first grammarian of whom there is any mention is the legendary Agastya, of whose works we may perhaps have a few surviving fragments in the commentaries of later authors. The first Tamil grammar to be preserved intact is the *Tolkāppiyam*, whose actual date of composition is unknown. It is certain, however, that its author, known as Tolkāppiyar, modeled his

work on the Sanskrit grammar of Pāṇini; very possibly he lived sometime during the 5th century A.D. In addition to the matters belonging to grammar as understood in the Occident, the *Tolkāppiyam* contains lengthy expositions on various aspects of literature, including prosody, rhetoric, word usage, and themes treated in poetry. The next major grammatical work is the 15th century *Nannūl* (*Good Treatise*), which still serves as the standard grammar in Tamil schools.

A third type of early writing is exemplified by the *Kural* (literally, couplet), perhaps the most widely known Tamil classic. This is a work of didactic morality whose 1,330 couplets are remarkable for their economy and clarity of style, for the wide range of human situations for which they provide guidance, and for their unique blend of worldly wisdom and idealistic ethics. The *Kural*, or *Tirukkural* (*Sacred Kural*), as it is generally called, inspired many poets to produce similar works. Pre-eminent among these later didactic works is the *Nālaṭiyār*, a collection of 400 quatrains. It shares with the *Kural* a position in Tamil literature that may be compared to that occupied by the King James Bible in English literature, for all three are prized both for their artistic merit and for their religious content.

There is also a class of religious writing which is lyrical and mystical rather than didactic. This body of literature is an outgrowth of the Hindu revivalist movement which arose in south India in the latter half of the 1st millennium A.D. in reaction to the spread of Jainism. Foremost among these Hindu religious lyrics is the *Tiruvāsakam*, a hymn of devotion to Shiva.

The *kāvya* (epic poem) is represented by a number of important works, including the Tamil versions of the *Mahābhārata* and *Rāmāyana*. Other well-known examples of *kāvya* poetry are *Silappatikāram* and *Manimēkalai*, both romantic tales of the adventures of a saintly heroine who, by virtue of miraculous powers and the help of the gods, passes through many trials to attain salvation.

Beginning in the 19th century there has grown up a considerable body of literature written in a prose style that approximates the spoken language and includes plays, novels, biographies, and short stories. In the 20th century there has also been a great increase in the number of Tamil periodicals, and these devote much space to contemporary writing.

Kannada (Kanarese) Literature.—The oldest extant Kannada work is the *Kavirājamārga*, a treatise on poetics written by King Nripatunga (r. 815–877 A.D.). Since it contains references to several older writers, however, the beginnings of Kannada literature must be ascribed to a still earlier period. In the 10th century lived one of the major figures of Kannada poetry, Pampa I, whose chief works are the *Adipurāṇa* and *Vikramārjunaviṣaya*; Chavūṇḍarāya, who wrote one of the earliest known prose works in Kannada, an account of the Jain saints called the *Chavūṇḍarāyapurāṇa*; and Nāgavarma I, who produced the first work on prosody, the *Chhandōmbudhi*. As is true of the other literatures of India, much of Kannada writing in this and later periods is religious in inspiration and sectarian in content.

Among the most important figures in Kannada poetry are Nāgavarma II and Nāgachandra, who lived in the 12th century; Kēśirāja (fl. 13th century), who wrote the best-known Kannada grammar, *Sabdamanidarpaṇa*; and Chikkupā-

dhyāya, Shadaksharadēva, and Lakshmiśa, of the 17th century. Later poets are, in the 19th century, Aliya Lingarāja and Chandrasāgaravarṇi; and in the 20th century, B. M. Srikantia, D. R. Bendre, K. V. Puttappa, and Madhura Chenna. The drama, the novel, the short story, and the essay have all been extensively cultivated since the early decades of the 20th century.

Malayalam Literature.—The earliest extant Malayalam work is the *Rāmācharitram*, attributed to a 13th century raja of Travancore. Prior to that time the literature produced in the Malayalam-speaking part of India was written either in Sanskrit or in Tamil, and even after it had become customary to compose literary works in Malayalam the practice of writing in Sanskrit persisted. Those works not written in Sanskrit very often did not employ a pure Malayalam, but rather a mixture of the two known as *manipravālam* (literally, string of gems and coral). In the period from the 13th to the 16th century a favored type of composition was the song or ballad, frequently either heroic or devotional. A classic work is the *Kṛṣṇagāthā* of Cheruśseri Nampūtiri, written in a simple Malayalam, and thus appealing to a wider readership than the *manipravālam* poetry, which was composed primarily for the learned. An outstanding example of the latter type is the *Chandrotsavam*, an account of a village festival.

Among the more important literary figures of the period from the 17th to the 20th century are Tunchathu Ramanujan Eluthachchan, Kunjan Nampiyar, Kerala Varma Valia Koil Tampuran (d. 1914), Kunhikudtan Tampuran, and Kochunni Tampuran. It was during this period that the two characteristically Malayali art forms were developed: the *kathakali* and the *tullal*. The first is a drama-pantomime in which the verbal text, sung by the musicians, is represented by the gestures, facial expressions, and dance movements of a very few elaborately costumed dancers performing on a bare stage; each action of the dancers has a meaning so precise that the spectator can follow the development of the story even without the vocal accompaniment. The similar *tullal* (literally, dance) is a poem accompanied by music and dancing.

Telugu Literature.—Possibly the oldest extant literary work in Telugu is a version of the *Mahābhārata* begun by Nannayya in the 11th century, almost completed by Tikkana in the 13th century, and finished by Yerrapregada in the 14th century. These three poets are traditionally regarded as the founders of Telugu literature. Other prominent figures of the earliest period were King Nannichoda, who wrote *Kumārasambhavam* (*Origin of the God Kumāra*) under the inspiration of Kālidāsa's Sanskrit *Kumārasambhava*; Palkuriki Somanātha (fl. 12th century), who wrote the first known *śataka* (a set of about 100 verses addressed to some person or god); Śrīnātha (1365-1440), whose works include *Kṛidābhīramam* and *Palnātivīracharitramu*; Vemāna (fl. early 15th century), who wrote widely known *śatakas* which have been translated into English; and Bammēra Potana, who wrote a Telugu *Bhāgavatamu* after a Sanskrit original.

The period from the 16th to the end of the 19th century is noted for the predominance of two literary forms: the *prabandha*, a highly conventionalized epic poem, and the *śataka*. Examples of the *prabandha* are Allasāni Peddāna's *Svārochishamanusambhavam*, the *Vasucharitramu* of

Ramarajabhushana (fl. late 16th century), Nandi Timmana's *Pārijātopaharaṇam*, Krishnadeva Raya's *Amuktamālyadā*, and Tenali Ramakrishna's *Kalāpūrnodayam*. The so-called *prabandha* period lasted until the end of the 17th century, when the *prabandha* gave way to the *śataka*. Much of the *śataka* literature was written during the time when the political power of Andhra (as the land of the Telugu people is sometimes called) was being crushed by the Muslims, and these *śatakas* reflect Andhra reaction to Muslim domination—first despair, and then a spirit of resistance.

The 17th and 18th centuries saw the growth in importance of prose and the drama. The first important work in prose, Raghunatha Raya's *Vālmikīcharitram*, was written in the 17th century, and in the 18th century Kandurti Venkata-chalakavi produced prose versions of several Sanskrit epics. Toward the end of that century appeared the first Telugu novel, the *Rājāśekhara-charitramu* of K. Viresalingam, whose works combine high artistry with a great zeal for social reform. In the drama there were many translations from Sanskrit and English and a wealth of historical, social, religious, and satiric plays. The best-known social drama is *Kanyāśulkam* (*Child Marriage*), by Gurazada Apparao, which ridicules certain traditional Hindu practices.

In the late 19th and early 20th centuries two new kinds of poetry developed: a romantic type inspired by John Keats and Percy Bysshe Shelley, and a poetry of social protest with Marxist overtones. Devulapalli Krishna Sastri, Abburi Ramakrishna Rao, and Rayaprolu Subbarao (1896-) are representative of the romantics, while Sri Sri (pseudonym of Srirangam Srinivasa Rao), Bairagi, and Arudra belong to the school of social realism. Meanwhile, the older tradition of Telugu poetry has been maintained by men like Tirupati Sastri and Venkata Sastri, while Visvanatha Satyanarayana and a few others seek a balance between the classical and the newer poetry.

LEIGH LISKER,
Assistant Professor of Dravidian Linguistics,
University of Pennsylvania.

FOLK TALES

Much of Indian fiction consists of folk tales—stories collected from oral narration. Since the first volume of such tales, Mary Frere's *Old Deccan Days*, appeared in 1868, many others have been published, sometimes as collections in book form or in periodicals and sometimes as insertions in works dealing with travel, anthropology, religion, or history. Folk tales have come from every part of the country and represent all of the major and many of the minor languages. Some few have been published in their original tongue, but most only in English translation. Narrators have ranged from the completely illiterate to the highly educated. The stories represent all the usual folklore types—cosmogonic, cosmological, and divine myths; place and hero legends; animal stories; tales and adventures; stories of cleverness, stupidity; the marvelous, exaggeration; anecdotes; and jokes. There are long ballads sung or chanted, generally with some simple musical accompaniment, in a public or semipublic setting, and there are simpler and shorter narratives sung in homes or before small audiences. The purpose of a tale may be worship, moral edification, or simple entertainment. Some stories are meant for the nursery; others may be subtle or satirical, appealing to the worldly,

the shrewd, the sophisticated.

Indian fiction illustrates a process of mutual feed and feedback between literature and folklore, both of whole stories and of separate motifs and incidents. A story or a motif may have originated in an illiterate community and have made its way into literature, to exist thereafter in both oral and literary forms. Another story or motif may have appeared first in literature. But in India, which has an extensive and ancient literature as well as a large illiterate population, few stories or motifs have maintained a long uninterrupted existence through oral transmission. Moreover, a story or a motif used in literature often has not remained segregated from folklore. Rather the literary form has often influenced the oral. The oral tradition seems to deteriorate; a story may become thin and ill constructed and waste away into virtual extinction. It may then be refreshed from literature, and studies have shown the direct dependence of many folk tales upon literary forms. Furthermore, many stories or motifs have been planted in the oral fiction from literary sources, sometimes from Indian sources, not always easy to identify, and sometimes from non-Indian sources, especially Persian and Arabic, when the borrowing may be clear. By a reverse process, Indian stories have been transmitted through literature to regions outside India, to become incorporated in the folklore there. Buddhist stories have gone by way of the *Jātaka* collection and other works to Ceylon, Burma, Malaya, Thailand, Cambodia, and Indonesia, and secular tales and Hindu religious legends have gone to some of these regions through such media as the *Panchatantra* (Sanskrit *Pañcatantra*) collection or the Hindu epic *Rāmāyaṇa*. Many have also gone to Tibet, central Asia, China, Iran, and Arabia, and some to Europe. In the regions of India where there is a strong literary tradition, the quality of the oral tales is likely to be better than in those with little or no literary tradition. For example, in the hill regions of Madhya Pradesh, where numerous tales have been collected from peoples whose languages are unwritten, the stories are often poor in plot and detail, while the narrators rarely seem able to sustain a long narrative.

There is much repetition in both oral and literary tales of motifs, themes, and incidents, and it is impossible to separate the one class of fiction sharply from the other. There are a few motifs, such as the life index or life token, which have a wide prevalence in the folklore and yet only rare occurrence in the literature, and a few other motifs and even story types which are limited to one or two peoples, such as the Santals and the Hos, speakers of nonliterate languages, whose dependence upon Indian literature for their fiction is slight. Throughout the areas with literatures, however, there is a great deal of fiction material which is held in common.

Regional Studies, University of Pennsylvania.

INDIAN LITERATURE IN ENGLISH

With the introduction and spread of English education in India after 1835, many Indians began

to write in English, and while the greater part of creative writing since the mid-19th century has been in the vernacular languages, a considerable body of material in English has accumulated. This material varies greatly in quality, but at least a few Indians writing in English have become masters of style and of their chosen form.

Fiction.—The novel and the short story, both of which have been borrowed from the West, are popular means of expression in India. The Bengali novel *Alāler Gharer Dulāl* (*The Spoilt Child*, 1858), by Piari Chand Mitra, is generally considered the first Indian novel. As in this earliest example, written, according to the author's own statement, to depict the unfortunate results of improper upbringing, many later Indian novelists have been greatly concerned with social problems and have produced works designed to call attention to the need for reform. This has been true of those who wrote in English as well as of writers in the vernaculars, and one of the foremost 20th century Indian writers, Mulk Raj Anand (1905–), falls into this group. His novel *Coolie* (1936) is the story of a young, unsophisticated boy from the hills of north India who makes a bare living in a series of menial jobs until, working as a ricksha puller, he contracts tuberculosis and dies. *Untouchable* (1935) depicts a day in the life of a boy belonging, as the title indicates, to the lowest class of society, while *Two Leaves and a Bud* (1937) deals with the hardships of workers on a tea plantation in Assam.

R. K. Narayan (1906–) is a writer of a very different sort. His aims as a novelist are more purely artistic, and there is nothing of the tract in the series of novels describing the life of Malgudi, a fictional town in south India, and its people. *Grateful to Life & Death* (1953), *The Printer of Malgudi* (1957), and *The Guide* (1958), to name three titles published in the United States, have, with his other novels, won high praise from both Indian and Western critics.

India's struggle for independence, as might be expected, provided the theme for many novels. Of these, one of the earliest written in English is *Kandan the Patriot*, by Kaneripatna Sidhanatha Venkataramani (1891–), a south Indian writer whose inspiration for this novel, published in 1932, was the Gandhian movement. Similarly, *Kanthapura* (1938), by Raja Rao (1909–), is concerned with the effect of the noncooperation movement on the life of a small village. Another writer, Khushwant Singh, in his novel *Mano Majra* (1956), chooses for his scene a village on the border between India and Pakistan and describes events which took place at the time of partition in 1947.

The modern short story finds a ready market in numerous English-language periodicals published in India, and each of the novelists mentioned above has published one or more volumes of stories. With Iqbal Singh, Mulk Raj Anand edited a volume entitled *Indian Short Stories* (1947), which contains some of the best of those written in English as well as translations of stories written originally in the vernaculars. Another short story writer, who is also a poet, Manjeri S. Isvaran (1910–), has vividly portrayed south Indian scenes and characters in a number of collections.

Autobiography, Poetry, and Drama.—Like the novel and the short story, autobiography is a

new literary genre in India. The beautifully written *Autobiography* (1936; new ed. entitled *Toward Freedom*, 1941) of Jawaharlal Nehru (1889–) is outstanding, but other men of renown in politics, religion, science, and letters have also left us records of their life and times. In addition, *The Autobiography of an Unknown Indian* (1951), by Nirad C. Chaudhuri (1897–), is noteworthy, and *The City of Two Gateways* (1950), by Savitri Devi Nanda, presents an interesting account of the life of a young girl growing up in north India.

Among poets who wrote in English, Toru Dutt (1856–1877) and her sister, Aru Dutt (1854–1874), were the earliest to achieve recognition. Their first work, *A Sheaf Gleaned in French Fields* (1876), consists of English translations of French poems. Since both girls died very young, however, their contribution was slight. Sarojini Naidu (1879–1949) is perhaps the most famous Indian poet who chose English as a medium. Her first book, *The Golden Threshold*, was published in 1905, and her third and final book, *The Broken Wing*, in 1917. In later years she devoted her talents to the struggle for independence and won a prominent place in the Indian National Congress. Her work has had considerable influence on younger poets.

Sri Aurobindo (Aurobindo Ghose, 1872–1950), who was known primarily as a religious leader and as the founder of a religious colony in south India, was also famed for his writing. His *Collected Poems and Plays* were published in 1942, and his epic poem in blank verse, *Savitri: A Legend and a Symbol*, in 1950–1951. His poetry is mystical and philosophical, and a number of poets writing in both English and the vernaculars have come under his influence. Of the first group, Dilip Kumar Roy (1897–), a novelist as well as a poet, and K. D. Sethna (1904–) are perhaps the best known.

Indian writers in English have devoted relatively little attention to drama, no doubt because opportunities for production are limited. Besides a few novelists and poets who have experimented with playwrighting, Bharati Sarabhai, who wrote *The Well of the People* (1943) and *Two Women* (1952), deserves mention.

12. SCIENCE

ANCIENT AND MEDIEVAL PERIOD

There is little Indian scientific or technical literature before the 5th century A.D. which can be dated accurately. But a people capable of making the Iron Pillar of Delhi and the Sultanganj copper colossus of Buddha (c. 400 A.D.), and of hewing out blocks of sandstone 50 feet long and 4 feet square (3d century B.C.), carving them into perfect roundness, giving them a wonderful polish which cannot be duplicated even in the 20th century, and transporting them over distances of several hundred miles, must have attained considerable proficiency in metallurgy and engineering.

The *Kautilya Arthaśāstra*, discovered in 1909, opens up a world of life and thought entirely different from that represented by the religious and philosophical Vedic literature. Kautilya was the prime minister of Chandragupta (r. 321?–?297 B.C.), first of the Maurya emperors, and

his book deals with every phase of government as regulating all matters of worldly life. Sections are devoted to precious stones, ores, metallurgy and mining, roads, trade routes, irrigation, medicine, trees, plants and poisons, ships and shipping, cattle, horses, elephants, chemistry, mechanical contrivances, and other technical matters.

It is probable that only the nucleus of the book can be as early as the 4th century B.C., and that the extant work is a composite based on the tradition of a school. No one, however, has argued for a date later than the 4th century A.D. for any part of it.

We now know that the Hindus were one of the greatest navigating and colonizing peoples of antiquity. At least from the 1st century A.D., and probably from three or four centuries before that time, Indian culture was the dominant factor throughout Indochina from Burma to China and in the islands from Sumatra and Java to the Philippines.

Language and Grammar.—The work of the Hindus on the systematic analysis of language reached a much higher point than that of any other people of antiquity. The grammar of Pāṇini (fl. probably not later than 500 B.C.) is the earliest scientific grammar in the world and one of the greatest ever written. It was the discovery in the late 18th century of Sanskrit and the Indian methods of analyzing language that revolutionized the Western study of language and led to the modern science of comparative philology.

The most striking feature of Sanskrit grammar is its objective resolution of speech and language into their component elements. Long before Pāṇini, who names over 60 predecessors, the sounds represented by the letters of the alphabet had been arranged in a systematic form, and the sounds in each group had been ordered according to the places in the mouth where they are produced. Words were analyzed into roots, from which complete words grew by the addition of prefixes and suffixes.

The study of language in India was as objective as the dissection of a body by an anatomist. It would be strange if this empirical attitude had been confined entirely to linguistics.

Geometry.—Undoubtedly the oldest works of Indian mathematics are the *Sulvasūtras* (Sūtras of the cord), which form part of the Vedic *Kalpasūtras*. While these texts are primarily geometrical, they seem to indicate the beginnings of mathematics. They deal with the building of altars and sacrificial places, and discuss such matters as the construction of squares and rectangles, the relation of the sides to the diagonals, and the construction of equivalent squares and rectangles, equivalent circles and squares, triangles equal to squares and rectangles, and squares equal to two or more given squares or to the difference of two given squares.

Although the date of the *Sulvasūtras* is unknown, it is probable that they were written as early as the 3d or 4th century B.C. Moreover, altars and sacrificial places of the same shape and construction are described in the much older Vedic literature. None of their geometrical constructions occur in later Indian texts, nor did they have a formative influence on the further development of geometry. The Vedic sacrificial ritual was replaced by temple worship, and later development was along the lines of arithmetic and algebra.

Hindu-Arabic Numerals.—From a very

early period the people of India were preoccupied with problems involving numbers, and they soon developed names for classes of numbers mounting by powers of 10. Such enumerations led more easily to the discovery of place value than the clumsy Roman method or the Greek method of counting by myriads. By the 5th century A.D. calculations were made by means of nine numerical symbols, with or without a sign for zero. These were used with place value so that they sufficed for the expression of all possible numbers. In the scanty Indian inscriptional material the earliest certain use of a symbol for zero appears in the 9th century, and symbols for the other nine numerals occur a century or two earlier. Their employment in inscriptions in Indochina goes back to 604 A.D., however, and their usage there doubtless was derived from India.

Since most of the early literature and inscriptions were written in verse, symbols could not be used, and numerical words were employed. *Sūnya*, meaning "empty" or "vacant," was used to indicate a vacant place in the numeration. Later a symbol, a dot or small circle, was used instead. About 800 A.D. the Arabs translated the word by *sifr* (vacant), and this later developed into the English cipher or zero.

In two Sanskrit texts of the early 6th century A.D., the *Sūryasiddhānta* (i, 29) and the *Brhatsamhitā* of Varāhamihira (viii, 20), words were used in place of numbers and were given in a definite order so that the numbers denoted by the words would be applied from right to left. The *Yogabhāṣya* (iii, 13), also of the 6th century, says, "Thus the same stroke is termed one in the unit place and ten in the ten's place and a hundred in the hundred's place." Surely a system with place value is implied. Brahmagupta (fl. early 7th century) gives rules for arithmetical operations with zero, as does Varāhamihira (b. 505?). In Subandhu's *Vāsaavadattā* (early 7th century) is the statement that the stars in the sky are like zeros put there by the Creator to indicate the nothingness of this world of transmigration.

The use of a symbol for zero may be later than that of the other nine symbols. Perhaps a board divided into perpendicular columns was used, the columns having the place value of units, tens, hundreds, thousands, and so on. After the discovery of place value either such a board with columns or a sign for zero would be necessary.

The forms of the numerals which we use today and call Arabic numerals were learned by the Arabs from India in the 8th century, but a passage from the Syrian Sēbōkt (662 A.D.) furnishes the earliest known reference outside India to Indian numerals: "The subtle discoveries of the Hindus . . . their clever method of calculation, their computation which surpasses words, I mean that which is made with nine signs."

Arithmetic and Algebra.—The classical period of Indian mathematics begins with Āryabhata (b. probably 476 A.D.) and extends to Bhāskara (b. 1114). Āryabhata's section on arithmetic culminates in the general solution in whole numbers of indeterminate equations of the first degree. Of Bhāskara's cyclic method of solving indeterminate equations of the second degree, Hermann Hankel, the well-known historian of mathematics, remarked that it was the finest thing in the theory of numbers before Joseph Louis Lagrange in the 18th century. In algebra the Hindus went

beyond the Greeks, and there is no proof of foreign influence on Indian mathematics.

The Hindus developed the sine function in computations connected with angles and with the circle. While the Greeks used a trigonometry of cords (the ratio of the cord to the diameter), the Hindus considered the ratio of the half cord to the radius a fundamental, and modern trigonometry rests on this foundation. The word *jyā* or *jīva* was first used by Āryabhata. Abbreviated from *ardhajyā* or *ardhajīva* (half cord), it means "bowstring." It was transliterated into the meaningless Arabic *jiba*, whose consonants allowed later writers to substitute the word *jayb*. This was subsequently translated into Latin as *sinus*, from which the word *sine* is derived.

Astronomy.—Classical Indian astronomy is now only of historical interest, although there seems no doubt that it exercised a formative influence on early Arabic astronomy and therefore had some effect on the medieval astronomy of Europe. In the astronomical literature of the third period, which begins at the latest in the 5th century A.D., the earth is described as a motionless globe of which Mount Meru is the axis, and around which the sun, moon, five planets, and the other heavenly bodies revolve. The sun, moon, and planets move more slowly than the stars and therefore change their places in relation to them. The true places of the planets in relation to their mean places are calculated by means of epicycles. The inclination of the ecliptic to the equator is known, and the positions of the heavenly bodies with reference to both are calculated. The procession of the equinox also is known. Moreover, the real cause of eclipses of the sun and moon is recognized, and the relations of these bodies are so well known that eclipses are calculated with great accuracy. The sexagesimal division of the circle is used. Substantially, this represents the point reached in Greek astronomy by the time of Ptolemy (2d century A.D.).

The system of the *Sūryasiddhānta*, the only one of five old Indian astronomical works to be preserved, was continued in approximately the same form from Āryabhata to Bhāskara. During this entire period there was little development in theory, the method of calculation continued unchanged in essentials, and only minor corrections in the numerical elements were made. Noteworthy is the assertion of Āryabhata that the earth rotates on its axis, but this theory remained isolated and was not followed by later works.

It is uncertain how much of Indian astronomy was original and how much was borrowed from the Greeks. Greek influence on Indian works of astrology is undeniable, and some words of Greek origin are found in later Indian works on astronomy. Of these the most significant is *kendra* (Greek *kentron*, center), since the center of the epicycle coincides with the mean place of the planet.

Medicine.—The beginnings of Indian medicine can be traced back to the magical charms of the Atharva Veda, but classical Indian medicine dates from Charaka and Suśruta (somewhere between the 1st and 4th centuries A.D.). The works of both were translated into Arabic about 800 A.D. While Charaka is essentially medical, Suśruta deals primarily with surgery. The osteology of these texts proves that careful empirical observations must have been made. Suśruta remarks: "No accurate account of any part of the body, including even the skin, can be rendered

without a knowledge of anatomy. Anyone who wishes to acquire a thorough knowledge of anatomy must prepare a dead body and carefully examine all its parts. For it is only by combining ocular observation and the information of text-books that thorough knowledge is obtained." He continues with considerable detail concerning methods of procedure. There is no trace of Greek influence on Indian medicine.

Theology and systems of abstract philosophy submerged the further development of a scientific attitude of mind in India until modern times.

Wales Professor of Sanskrit Emeritus, Harvard University.

MODERN DEVELOPMENTS

The introduction of English education in the 19th century marked the beginning of a scientific revival in India. From 1855 onward arrangements were made for the teaching of science in the newly established schools and colleges. After the passage of the Universities Act of 1904, Indian universities were enabled to provide laboratory facilities and staff for science teaching, and progress in all sciences became noticeable.

Science Revival.—The revival of interest in science was given impetus by the efforts of such learned societies as the Asiatic Society in Calcutta, scientific surveys, and government scientific officers. The pioneering work of the four government survey departments helped to lay the foundations for the development of science. The Trigonometrical Survey, renamed the Survey of India (1878), was responsible for mapping the subcontinent; the Botanical Survey (1889) and the Zoological Survey (1866) embarked on an appraisal of Indian flora and fauna; and the Geological Survey of India initiated an assessment of mineral resources.

By the beginning of the 20th century many Indian universities had developed postgraduate departments in various sciences. The government of India established research institutes, among them the Imperial Agricultural Research Institute, Pusa; the Central Research Institute for medical research, Kasauli; and the Forest Research Institute, Dehra Dun. In addition, the provinces started institutions for medical and agricultural research, and private benefaction was responsible for the Indian Institute of Science in Bangalore, the Indian Association for the Cultivation of Science and the Bose Research Institute in Calcutta, and other institutions.

The early decades of the 20th century witnessed the formation of scientific societies. The Indian Science Congress Association (1914) provided a forum for research workers from various parts of the country. Three national academies—the National Institute of Sciences of India, the Indian Academy of Sciences, and the National Academy of Sciences—came into being in the 1930's.

The first half of the century was also notable for achievements by individual scientists, like those of the great mathematical genius Srinivasa Ramanujan (1887–1920); Sir Venkata Raman (1888–), whose name is associated with the Raman effect; and Sir Jagadis Chandra Bose (1858–1937), whose studies on plant life opened a new trail. The pioneering work of Sir Ronald

Ross (1857–1932) on malaria and the contribution of Birbal Sahni (1891–1949) to paleobotany also merit mention.

Science and the Nation.—Important as these developments were, scientific research in India had hardly any impact on national development. Research was mainly academic and largely the concern of the talented few in universities and research institutions. While some attention was paid to the improvement of primary products, the emphasis was on raw materials with export potential. The exigencies of two world wars and the dawn of independence changed the picture entirely. A proper appraisal of the scientific resources of the country vis-à-vis national needs was then taken up. The lacunae in the research effort were sought to be filled, and attempts were made to establish viable organizations for promoting research. The tempo of technological education was accelerated, and institutes with postgraduate facilities for research in engineering and medicine came into being.

There are three autonomous all-India councils, each with its network of laboratories and stations, dealing with problems of research and development: the Council of Scientific and Industrial Research, the Indian Council of Agricultural Research, and the Indian Council of Medical Research. The Atomic Energy Commission is concerned with research and development of nuclear energy, and responsibility for research in the defense field vests in the Defence Science Organization. Moreover, technical departments under the various ministries contain research divisions. Among other institutions, mention may be made of the Indian Bureau of Mines, the Oil and Gas Commission, and the Indian Standards Institution.

Rapid developments under the national five-year plans have imposed new responsibilities for intensifying scientific effort. A scientific policy resolution passed by the Indian Parliament in 1958 accepted these responsibilities and assured continuing support for scientific inquiry.

M. S. THACKER,
Secretary, Ministry of Scientific Research and Cultural Affairs.

13. RELIGION AND PHILOSOPHY

There are no major variations of belief, practice, or history within each religion of the Indian subcontinent based upon geographical differences. For this reason, the religions of India and Pak-

RELIGIONS OF INDIA AND PAKISTAN

Nontribal; others	47,148	11,712 ⁴

¹ Source: *Census of India, 1951*, Paper No. 2, 1953, *Religion*, Table D-II. The census did not include Jammu and Kashmir and certain tribal areas of Assam, whose combined population is estimated at 4,971,000, and the figures for religion also exclude 268,602 persons in the Punjab whose records were destroyed by fire before the information on religion could be tabulated. Many persons counted in the previous censuses as animists were returned in 1951 as Hindus or Christians. ² Source: *Census of Pakistan, 1951*, vol. 1, Table 6, Religions. The total excludes 207,000 persons not of Pakistani nationality. ³ Not differentiated. ⁴ Corrected figure.

istan are treated together under the following headings: (1) religion and philosophy of Indian origin, (2) Islam, and (3) Christianity. The religious distribution of the population of the two countries is shown in the accompanying table. About 20,868,000 of India's Muslims live in the northern and eastern region of the country, and about 9,239,000 of Pakistan's Hindus live in East Pakistan.

For the religion of the Parsis of the subcontinent, see **MISSIONARY MOVEMENTS—Zoroastrian Missions**; **PARSIS or PARSEES**; **ZOROASTRIANISM**.

RELIGION AND PHILOSOPHY OF INDIAN ORIGIN

Modern Hinduism and Brahmanism.—Hinduism is more than a religion: it is a total way of life, including social order, law, science, literature, art, and philosophy as well, for in India philosophy and religion have never existed separately from each other. Incorporated in it is the body of Indo-Aryan thought and ritual cultivated by the learned class called Brahmins (*Brāhmaṇa*) and stemming from the Veda, but altered and expanded in post-Vedic times as the Aryan invaders of India blended with the non-Aryans whom they met there. This constitutes the "higher" religion called Brahmanism. It is contrasted with a mass of belief subliterate in origin and coming from all the racial and cultural elements known to have existed in India. This is the "lower" religion or popular Hinduism.

Beliefs.—Hinduism countenances every shade of theological belief, starting at the bottom with the most naive form of animism, passing through polytheism and monotheism, to reach at the top a rigorous philosophical monism. It has no formal creed, no standardized cult practice, no controlling ecclesiastical organization. Its adherents usually ascribe incontrovertible authority to the Vedas, but refer to that ancient collection less frequently than to later texts. For theology and mythology they rely upon the two great Sanskrit epics, the *Mahābhārata* and the *Rāmāyana*, which grew up slowly between 400 B.C. and 400 A.D., and versions of them in modern vernaculars, such as that in Hindi by Tulsī Dās (1532-1623); the *Purāṇas* (also in Sanskrit), the most important of which were probably composed between the 6th and 13th centuries; and a class of texts called *Māhātmya* (usually recent works, generally in Sanskrit), which purvey local religious legends. For cosmogony and cosmology they accept the statements of the *Purāṇas*. For religious law they refer less to the oldest legal textbooks called *Sūtras* (thought to be from before the 4th century B.C.), which are closely attached to the Vedas, than to the later (2d to 7th century A.D.) *Shāstras* (*Sāstra*). In cult practice they do not employ the old and elaborate fire and soma rites of the Vedic ritual texts known as *Brāhmaṇas* (10th to 7th century B.C.), but use an infinite variety of later-developed ceremonies.

To some Hindus all phenomenal existence is only relatively real—these are adherents to pure monism. Others may accept much simpler concepts. Probably the greatest number of those who recognize authority in the Hindu scriptures accept in some form, though often with considerable modification, the theory of the *Purāṇas* concerning the recurring dissolution (*pralaya*) of the universe and its re-creation (*pratisarga*). The elements of the universe are matter (*prakṛti*; Sanskrit *prakṛti*), which has three qualities

(*guna*; Sanskrit *guna*), namely, goodness (*satva*), passion (*rajas*), and darkness (*tamas*). Against matter is contrasted spirit (*puruṣa*; Sanskrit *puruṣa*). From these, under impulse from the self-existent *Brahmā* (masculine), who is sometimes equated with matter or spirit or with both, evolve all the gods, all other animate creatures, the earth, the heavens, the hells.

Conceptions of deity also vary. On medium and high intellectual levels Hindus are almost always adherents of sects or cults devoted either to the great deities Shiva (*Śiva*) and Vishnu (*Viṣṇu*) or to lesser deities associated with them. Vishnu may be worshiped in his incarnations (*avatāras*; Sanskrit *avatāra*), of which the two most popular are Rāma Chandra, hero of the *Rāmāyana*, and Krishna (*Kṛṣṇa*), speaker of the religious lyric *Bhagavad Gītā* and hero of a large body of legend centered at Mathura. Vishnu's wife, Lakṣmi (*Lakṣmī*), is also honored as the goddess of prosperity; in the Krishna legend she is incarnated as the milkmaid Rādhā, Krishna's mistress. Another favorite is Hanumān, the monkey god who in the *Rāmāyana* helped Rāma rescue Sītā, Rāma's wife, whom the demon Rāvaṇa had abducted to Ceylon. Shiva is often worshiped as the phallic symbol (*linga*; Sanskrit *linga*), with which may be associated the female symbol (*yoni*) as the emblem of his wife, Pārvatī. His sons Kārtikeya or Skanda (god of war) and Ganeśa (*Gaṇeśa*), the elephant-headed god who removes obstacles and brings good fortune, are popular deities. Sectaries often wear distinguishing marks on their foreheads. Sectarian adherence, though sometimes polemical, need not be very strict, and a Shaiva (*Śaiva*, one belonging to a Shiva sect) may on occasion worship in a Vaishnava (*Vaiṣṇava*, belonging to a Vishnu sect) temple and vice versa.

A variation of Hinduism is adoration of the female principle or power called Shakti (*Śakti*), represented as a goddess. As the creative and effective energy in the universe, this is considered by devotees to be more important than the male principle, represented as a god, which is otherwise only unrealized potentiality. This type of worship, a variety of Tantrism (its texts are known as *tantra*), is directed toward Devī, meaning "goddess," the wife of Shiva, and otherwise called by such names as Umā, Pārvatī, Durgā, Gaurī, Bhavānī, Kālī, and Ambikā. She is the universal mother. Shaktism is either right handed or left handed, the chief distinction lying in the use of ritual by the latter group which involves erotic and magic practices.

On lower intellectual levels, Hindus may propitiate any of a large number of vegetation and fertility godlings, divinities of disease or misfortune, the village mother goddesses, ancestral spirits, the sun, and the moon. Trees, such as the variety of fig known as pipal, and stones may be treated as sacred; also animals, such as the monkey, the peacock, the cobra, and, in some cases, the tiger and the horse. Rivers, such as the Ganges, the Jumna, the Narbada, the Godavari, the Krishna, and the Kaveri, may be holy, and so, too, mountains, such as the Himalaya and the Vindhya Range. Astrology, divination, and the use of omens are common; the evil eye is feared.

On the highest intellectual level a Hindu seeks the one reality, whether conceived impersonally as Brahma (neuter) or theistically as Shiva or Vishnu. Once he succeeds, he may continue to live in the world but without emotional attachment

to it; it no longer has significance for him. He has passed above all the opposites—sorrow and joy, pain and pleasure, evil and good.

Hinduism accepts as not requiring proof the joint doctrine of rebirth and works (karma). Every living being at the time of death is reborn in a different form, either higher or lower, whether as a human being, an animal, a heavenly creature, or a hell dweller. From that existence it will again be reborn, and so on endlessly. This round of rebirth is called the *samsara* (Sanskrit *samsāra*). The precise form of each rebirth is always determined by the balancing, as in a mathematical equation, of the being's deeds (karma) in previous existences. Escape from the cycle of rebirth constitutes salvation—*moksha* (Sanskrit *mokṣa*), *mukti*, *nirvana* (Sanskrit *nirvāna*)—and is in theory the ultimate goal of every living being, but it is so difficult to attain that the aim is almost invariably only to improve one's condition in the next existence. Rarely does anyone strive for more than a long life, perhaps lasting a few million or billion years, in the heaven of some god. A being who attains salvation may do so through perfect performance of ceremonial works (karma), that is, ritualism; or through attainment of perfect knowledge (*jñana*; Sanskrit *jñāna*), essentially a philosophic goal, toward which the greatest help is the practice of meditation with the aid of the technique known as *yoga*; or through some deity's grace won by the worshiper's complete and loving devotion (*bhakti*); or by the prosecution of severe asceticism (*tapas*). In every case, strong emphasis is laid upon having a guru (spiritual preceptor), who may be viewed as little less than God.

Worship.—Places of worship range from the most primitive of wayside shrines, consisting of a stone set under a sacred tree and daubed with paint, symbolizing some form of divinity, to the most elaborate complex of structures constituting an enormous temple. Certain cities are especially holy to Hindus, the most holy being Varanasi (Banaras). Hindus use images freely in their worship as comprehensible symbols of a deity which in its true form is not apprehensible by human senses, though for the unsophisticated the use may be only that of idolatry. Worship may consist of offerings of flowers, fruit, grain, ghee (Hindi *ghī*, clarified butter), money, and, in some connections, animal sacrifice. A worshiper may appeal to the deity directly or through the agency of a priest. Worship is usually individual; an exception is the chanting of religious lyrics by a group under the stress of devotional emotion. In the temples ritual may be elaborate, involving the use of Sanskrit verses recited by scholarly priests, but many village priests know no Sanskrit and confine themselves to the use of vernaculars.

Religious authority vests in the Brahmins, who besides being custodians of the sacred learning constitute the priesthood. They officiate at religious ceremonies in homes or temples and are other men's vicars in dealing with the deities. As astrologers they cast horoscopes and then interpret them throughout a person's life to determine auspicious and inauspicious moments and conditions for specific undertakings.

Caste System.—The social structure of Hinduism is embraced in the caste system, which separates mankind into many separate groups. The word *caste* is a modification of the Portuguese noun *casta*, meaning "[pure] race or lineage," and is derived from the Latin adjective

castus (pure); the Indian term is *jāti* (Sanskrit *jāti*), meaning "group by birth." The various castes have different social precedence. At the top are the Brahmins, in traditional law constituting a highly privileged group, who have been the codifiers and formulators of the philosophy sanctioning the system and the directors of the instrumentality for enforcing its rules. They constitute about 7 per cent of the Hindu community. Caste is hereditary, and it is not possible to transfer from the caste in which one is born to another. Neither can a non-Hindu individual ordinarily become a member of a Hindu caste, though under certain conditions a group can slowly enter the system as a new caste.

The caste system prescribes strict regulations concerning marriage, which must usually be within the caste but outside the immediate family or clan; eating, which is subject to taboos and complicated rules respecting the acceptance of food and drink from members of other castes; and many other phases of human relationship. In its most extreme form it has imposed onerous disabilities upon those lowest in the scale, known as *Fifths*, who are estimated to comprise 20 per cent of the Hindu community. Traditionally these people performed the most degrading forms of work. They were held to pollute the higher castes through mere proximity and were required to live in separate quarters or in separate villages. Frequently they were denied access to wells, roads, schools, and temples used by the higher castes, and were forbidden by religious law to read or hear the recitation of the scriptures. In the 20th century these taboos, restrictions, and impositions have been greatly eased.

In Hindu theory each caste has a separate social function or occupation, but in practice the rule does not hold. Since the criteria are not sharply separated, the number of castes is impossible to determine. Endogamous groups of more than 500 members each probably exceed 1,000 in number, but most of these are of only local provenience. The castes are classified by the Hindus in five groups—in descending order of social worth. Brahmins, Kshatriyas (*Kṣatriya*) or Rajanyas (*Rājanya*), temporal rulers, and Vaisyas (*Vaiśhyas*; Sanskrit *Vaiśya*), commons (that is, merchant and artisan groups) are called twice born (*dvija*), because the boys in these three groups undergo a ceremony of initiation, whereupon ideally they enter upon their religious training. The two other groups are Sudras (*Shudras*; Sanskrit *Śūdra*), servants; and Pan-chamas (*Pañcama*, fifth) or outcastes, also known eclectically as untouchables, exterior castes, scheduled castes, depressed castes, pariahs, or, in Mohandas K. Gandhi's term, *Harijan* (God's folk). The last two groups have no ceremony of initiation; most of them are descendants of lowly groups that at one time or another achieved a place in Indo-Aryan society and religion. The fivefold classification also breaks down, since a caste may in one census assign itself to one of these groups but in the next to the group higher. Every caste, no matter how low in the scale, always knows another which it considers lower.

Ethics.—Man's duty (*dharma*) is to satisfy his caste rules and fulfill his caste functions, to honor the gods, to observe the ceremonies which ideally accompany every important aspect of life from conception to after death, and to perform miscellaneous good works, such as almsgiving, the undertaking of vows and pilgrimages, often

at specified times when great numbers of people gather in festivals, religious bathing, reverencing the Brahmans, and feeding the poor. In Hindu teaching from the time of the Sūtras, a man devoted most fully to religion should divide his life into four periods or stages (ashrama; Sanskrit *āśrama*): (1) celibate studentship (*brahmachārin*); (2) householder (*grhastha*), raising a family and fulfilling his worldly duties; (3) forest-dweller anchorite (*vānaprastha*), retiring with his wife to a remote place for religious duties and meditation; and (4) wandering ascetic (*sannyāsin*, *bhikṣu*), having severed all ties with family, living alone, subsisting on alms. This fourfold scheme is but rarely practiced today.

The outstanding ethical principle is ahimsa (Sanskrit *ahimsā*) or noninjury of living creatures, which Gandhi called nonviolence. The doctrine applies not only to mankind, but also to the animal world, varying in application toward the separate animal species but always demanding protection of bovines, which hold a position of peculiar sanctity in Hinduism. Acts violating one's duty constitute offenses against religion and may even be attended by ceremonial pollution. This may be absolved by paying penalties or by performing expiatory rites.

Hinduism has been an incorporating religion, accepting and legitimizing ideas, deities, and cult practices from many sources. It blends its widely varying beliefs and practices into a whole by admitting, without explicit statement, that men are not intellectually and spiritually equal. For this reason, it is unrealistic to expect all human beings to believe alike, pursue the same goals, have identical behavior, attain the same spiritual heights. Truth has one aspect to one person, another aspect to a second person, and still another to a third. Absolute truth can be achieved by only the rarest individual, but what any man sees is, within his limitations, truth for him. Similarly, man's conduct is governed by rules that vary according to his spiritual and intellectual capacity. In this relative view of life lies the sanction for the caste system. A person is born to the status that suits his attainments in consequence of his deeds in previous existences; the functions of that status are those which he should fulfill—he should not try to fulfill those of some other status, says the *Bhagavad Gītā*, even though he might perform them better than the person to whom they belong. The code of personal conduct under which he lives is the one suitable to his status and to him. A consequence of this view has been that in Hindu thinking there has been little concern about human rights; rather the emphasis has been put upon the fulfillment of duties.

The Hindu system is, therefore, marked with a high degree of tolerance and flexibility, and is capable of relatively easy adaptation to changed living conditions. Thus, caste rules may alter rather quickly. Early marriage of girls no longer is binding, and the seclusion of women is outmoded. Even the remarriage of widows has gained some degree of toleration. Though many detailed features have been altered in the 20th century, it would not be justifiable to assume that Hinduism as a system is vanishing. It has been strong enough in the past to persist in spite of many changes induced by intellectual or social pressures developing from within or by forces imposed upon it from outside. There has never been a time in the known history of Hinduism when it was not altering in some important re-

spect. Modern reforms are the 20th century illustration of an old and recurring phenomenon.

Early Indus Civilizations.—Inferences concerning the religion of the prehistoric early Indus civilization are drawn from sculpture, pottery figurines, seal designs, and other finds, especially of the Harappa period (c. 2500–1700 B.C.). The data give presumptive evidence of worship of a god who had characteristics similar to those of Shiva in historic times, of a cult of the Great Mother or Earth Goddess, and of phallic worship. Certain trees appear to have been sacred, including the pipal tree, which is sacred in Hinduism today. In some representations trees have associated with them female figures that may be fertility divinities. Various animals, including the tiger, elephant, buffalo, crocodile, rhinoceros, and mythical hybrid creatures, appear to have had sanctity. Symbols appear which reappear in historic India with religious significance, among them the swastika.

See also 16. *Prehistory*.

The Vedas.—India's earliest book, the Rig Veda (*Rgveda*), which was probably compiled by 1000 B.C., consists of 1,028 hymns composed by sages (*rishi*; Sanskrit *ṛṣi*) for use in the religious ritual of the early Indo-Aryans. Accompanying it and of almost equal antiquity are three other compilations: the Yajur Veda, which preserves the prose formulas used in early Vedic ritual; the Sāma Veda, which deals with the chants belonging to it; and the Atharva Veda, which provides for the private or household religion.

The religion of the Rig Veda derives in part from primitive Indo-European times, as in addressing the deified Sky Father, Dyaus Pitṛ (for etymology and meaning compare Greek Zeus Pater, Latin Jupiter), and the Earth Mother, Pṛthivī Mātṛ (for significance compare Greek Demeter, Latin Terra Mater). The most prominent deities and ideas in the Rig Veda, however, cannot be identified as primitive Indo-European. These include a class of superhuman beings known as asura, some of whom, the Adityas—Varuṇa, Mitra, Aryaman, Bhaga, Dakṣa (Dakṣa), Aṁśa—are benevolent, others of whom are malevolent, being demons (*rakṣas*). The chief god of the Vedic pantheon, Indra, is also hard to associate with any Indo-European figure. Because of his pre-eminence he is often called the sole (that is, supreme) god. Some of the Vedic mythic material associated with the asuras and Indra seems similar to items appearing earlier in the mythology of the Mesopotamian-Iranian region, through part of which the Aryans passed on their way to India.

The Rig Veda presents the universe as being in two main parts. One is that which men and gods inhabit; it contains light, heat, and moisture and itself has three parts, namely, the surface of the earth, the atmosphere, and the vault of heaven. This is called the sat (existent). The other main part is a place of darkness and horror called the asat (nonexistent), where demons lurk by day and whence they emerge by night. The central theme of Vedic mythology is the conflict between Indra, the champion of the gods and their king, and Vritra (*Vṛtra*, the encloser), personification of the hard covering within which

were originally contained the elements needed for creation of the sat. Vritra is usually described as a serpent, the malevolent leader of the demons. Indra slew him with his weapon (vajra) or, as is frequently said, burst open his belly. Out flowed the waters (*āpas*), often described complementarily as cows, to fill the celestial ocean. Marvelously they were pregnant with the sun. The universe now had moisture, light, and warmth, and creation could take place. Order (*rita*; Sanskrit *ṛta*) was established and put under the administration of Varuna, and in due time man was created. Every creature—man or god—had a personal function to fulfill as part of order. When he fulfilled it, he was living in accord with the sat and so achieving his highest good.

The Vedic cult centered about the fire sacrifice, which was personified as Agni, god of the sacrifice and the divine priest. Offerings included animals and ghee, but the most important was soma, an exhilarating drink pressed from some unknown plant and personified as the god Soma. The fire ceremony required an elaborate priesthood to summon the gods, recite the appropriate stanzas or prose formulas, sing the chants, perform the manual acts, offer the prayers, and direct the ritual. This priesthood was of prime importance, since the ritual was useless if not executed perfectly, and it was the origin of the Brahman caste.

Men and gods were mutually dependent: men sought prosperity, lineage, health, long life, victory in battle, and safety from demons, all of which the gods could provide; and the gods needed for their sustenance the rich offerings made in the sacrifice. The righteous dead, those who by their religious observances had won the favor of the gods, went to the realm of the blessed, where lived Yama, the first man, to rejoice there with him and the gods. On the way they were protected from the demons by the two heavenly dogs, Śabala (brindled) and Śyāma (dark). The wicked, however, had no such protection, but, fettered by their sins, were waylaid and overtaken by the demons and destroyed.

As the sacrifice became increasingly important and complex, various schools of priests arose for preserving its ritual, and these put their teachings into the form of literary works known as the Brāhmaṇas. The sacrifice itself came to be considered all powerful, operating mechanically as a kind of cosmic magic which, when properly performed, could compel even the gods to the sacrificer's will. Contemporaneously there also developed an interest in cosmogony outside the sphere of the Indra myth, and various explanations of the origin and operation of the universe are advanced. A kind of superdeism appears, centering around Prajāpati (lord of creatures). Or a world man, Puruṣa (*Puruṣa*, male), when sacrificed, provides the material of the universe. The sounds of the sacrifice, consisting of the crackling of the fire regarded as the voice of Agni and the chants of the priests, are viewed as all controlling; this idea appears as the feminine deity Vāc (voice). A strictly impersonal conception appears with respect to the idea of Tad Ekam (sole principle; neuter), from which all is evolved. These various speculations record the beginning of Indian philosophy.

Upanishads.—The Upanishads (*Upaniṣad*), probably beginning in the 7th or early 6th century

B.C., which appear as appendages to the Brāhmaṇas, extend the tentative Rig Vedic philosophical inquiries about the nature of the universe and in addition investigate the human psyche or soul. They do not develop these topics systematically, and the explanations offered in different Upanishads are not all mutually consistent. A frequent form of Upanishadic investigation starts with the conception of sleep and develops the idea of the four states of the soul: the waking state, dreaming sleep, deep (dreamless) sleep, and the fourth state (*turiya*), indescribable in terms of the senses, which is conceived as the final goal in man's search for the ultimate. Other passages teach that the soul is immanent in all creation, uniform in character, and the essential part of the individual. As described by the celebrated teacher Yājñavalkya, it is pure subject, distinct from all that is material, unknowable, capable of perceiving and of knowing all, yet unmatched by any second reality to be perceived or known. All else but soul is only relatively real. Duality is in the final analysis false; ultimate truth lies only in a monistic conception of the universe.

The identification of the human soul (*atman*; Sanskrit *ātman*) and the universal soul (*brahman*) on these terms is the supreme achievement of the Upanishads. Besides this monism, however, some Upanishads also express the view that both matter (*prakṛiti*) and soul (*puruṣa*) are real, being mutually exclusive and standing in complete contrast to each other. Both views have since persisted in Indian thinking, appearing in one form or another in the various philosophical and religious systems.

In the Upanishads appear the first suggestions of the doctrine of rebirth (metempsychosis; transmigration of the soul) and retribution for one's deeds (karma) in succeeding existences. The Upanishads also speak of engaging in meditation with the aid of yoga.

Much religio-philosophical speculation and doctrine appear in the great epic *Mahābhārata*, most conspicuously in the section known as the *Bhagavad Gītā*, which calls itself an Upanishad. Krishna, who is an incarnation of the god Vishnu, instructs Arjuna, leader of the army fighting for the right, and though admitting the approach to self-realization through works, provided they are performed selflessly, and through knowledge, emphasizes above all loving devotion (*bhakti*) to God. In the climax of the work, Krishna reveals himself in transfigured form as Vishnu, containing within himself the universe.

Formal Philosophies.—In the period of approximately 1,000 years from the time of the older Upanishads, or roughly from around 500 B.C. to 500 A.D., the six orthodox systems (*darshana*; Sanskrit *darśana*, view) of Indian philosophy were developed and given their classical form. These systems, which provide the intellectual basis for Brahmanic Hinduism, are (1) Pūrva or Karma Mīmāṃsā, "discussion of the first, or practical, part" of the Vedic religion; the formulation of its basic text is ascribed to Jaimini; (2) Uttara Mīmāṃsā, "discussion of the latter part" of the Vedic religion, often called Vedānta (end of the Veda); the formulation of its basic text is ascribed to Bādarāyaṇa; (3) Nyāya, "logical method," formulated in a text by Gotama (Gautama); (4) Vaiśeṣika, "differenti-

ation," the philosophy of atomism, ascribed to Kaṇāda; (5) Sāṃkhya, "reason" or "enumeration," which analyzes nature and is ascribed to Kapila; and (6) Yoga, which is primarily devoted to the technique of meditation and is ascribed to Patañjali. This is the Hindu order; the systems are described here in another order, reflecting the relationship of ideas.

Pūrva Mīmāṃsā.—This system rationalizes Vedic fundamentalism, that is, the literal meaning and application of the Vedas. It regards the Vedas as authorless and self-revealed, and therefore as authoritative. According to the Pūrva Mīmāṃsā, the world exists throughout eternity and is not subject to recurrent dissolution and re-creation. The system accepts the reality of both the soul and the material world. There are two kinds of acts. The first consists of those ordained by the Vedas. These are the Vedic sacrifices; by doing them one obtains heaven. The other consists of prohibited acts. By doing them and abstaining from ordained acts, one suffers a future life in misery.

Sāṃkhya.—This system gets its name either from the application of reason to the analysis of the soul and nature or from the 25 principles or true entities (tattva) which it numerates. The two basic contrasting entities are soul (puruṣa) and matter (prakṛiti). Souls are infinite in number and consist of pure intelligence. Each soul is independent, indivisible, unconditioned, incapable of change, immortal. It appears, however, to be bound to matter—prakṛiti, pradhāna (Sanskrit *pradhāna*), avyakta. At the beginning of an eon nature is in a state of rest or inertia. It has three qualities (guṇa), known respectively as goodness (sattva), passion (rajas), and darkness (tamas), which are in balance. But souls, because of their karma, begin to move; nature then stirs; the qualities fall out of equilibrium. From nature then evolve the other 23 principles. The first is intelligence (buddhi), also called the great principle (mahat tattva) or the great (*mahān*); from it evolves the process or organ of individuation (ahankāra; Sanskrit *ahankāra*, I-maker). The latter differentiates itself cosmically and individually. Cosmically it produces the five subtle elements (*tanmātra*) of earth, water, fire, air, and ether, from which are produced the corresponding five gross elements (*mahābhūta*). These are the objects of sense. Individually it produces the five senses (*buddhindriya*) of hearing, touch, sight, taste, and smell, which make contact with the gross elements; the mind; and the five organs of action (*karmendriya*). With only minor variations, this physiological psychology is common to Indian thought of all schools.

According to the Sāṃkhya, every individual has a subtle characteristic body (*linga-deha*) consisting of intelligence, individuation, mind, and the 10 organs of sensation and action. This is what transmigrates, being lodged in a gross body composed of the objects of sense. How soul has come to be associated with the subtle body is not made clear. Through knowledge the association may be terminated, and this separation constitutes salvation. The subtle body is dissolved, and the soul exists in isolation. To obtain knowledge the best means is to pursue the technique of yoga.

Yoga.—This system of philosophy is an extension of the Sāṃkhya. It formulates systematically the techniques of meditation known as yoga, a word which means "harnessing" or "control" and refers to the control and suppression of the activ-

ities of the mind and the sense organs so that these will not interfere with the soul in the attainment of self-realization. The Yoga system of philosophy postulates a god, Īśvara, who is really a particular soul, supremely possessed of knowledge, goodness, and power, no longer affected by karma. He helps a worshiper in the early steps on the road to salvation.

The first stage of the yoga technique is designed to cause the evolutes of intelligence (buddhi) to retract into intelligence, and this is accomplished by *kriyā yoga* (yoga of observances of physical acts) in five stages: (1) adoption of restraints (*yama*) from lying, killing, and other evils; (2) adoption of observances (*niyama*) of purity and other virtues; (3) use of posture (*asana*; Sanskrit *āsana*) suitable for meditation; (4) restraint of breath (*prāṇāyāma*); and (5) withdrawal of senses (*pratyāhāra*) from the objects of sense. Then comes the second main stage of yoga, known as superior or royal yoga (*rāja yoga*), in three phases (*saṃyama*): (1) concentration (dharana; Sanskrit *dhāraṇā*) of the intelligence on an object without wavering; (2) meditation (dhyana; Sanskrit *dhyāna*) as an uninterrupted mental state; and (3) trance (*samādhi*; Sanskrit *samādhi*), in which the individual is fully identified with the object of meditation.

See also YOGA.

Vaiśeṣika and Nyāya.—These were separate in origin but came to be combined in a common system. Both accept the idea taught by the Vaiśeṣika that the universe arises from atoms (*anu*; *paramānu*; *kaṇa*), and use a body of logic codified in the Nyāya. The Vaiśeṣika discusses the world under six categories (*padārtha*): (1) substance (*dravya*), (2) quality (guṇa), (3) movement or action (*karmaṇ*), (4) association (*sāmānya*), (5) difference (*viśeṣa*), and (6) inherence (*samavāya*). Later teachers add (7) nonexistence (*abhāva*). The idea of difference, that is, that differences in the universe arise ultimately from differences in the atoms, gives the system its name.

The Nyāya (method, rule) gives the rules of correct thinking. There are four ways of acquiring knowledge: (1) perception by the senses (*pratyakṣa*), (2) inference (*anumāna*), (3) analogy (*upamāna*), and (4) authority or credible testimony (*śabda*). Of these inference is the most important for acquiring philosophical knowledge. The Nyāya syllogism has five parts: (1) proposition, (2) cause, (3) illustration, (4) recapitulation of the cause or application, and (5) conclusion. The standard example is of the mountain and the fire: (1) the mountain is on fire; (2) because it is smoking; (3) wherever there is smoke there is fire; (4) the mountain is smoking; (5) therefore it is on fire. Causation is considered to be material or inhering cause, which is invariable and primary for any given object; and effective cause, which is variable and secondary. Between these two there is sometimes considered to be a noninhering or formal cause. In a carpet the threads are the material or inhering cause, the association of threads is the noninhering or formal cause, and the weaver's activities are the effective cause.

In its older form the Nyāya system appears to have acknowledged the force of karma and rebirth, but not to have recognized God. Both matter and soul were regarded as uncreated and eternal. The later Nyāya, as blended with the Vaiśeṣika, recognized a god who was an indi-

vidual soul, but unlike other souls was omniscient and omnipotent and not subject to transmigration.

Uttara Mīmāṃsā or Vedānta.—More than any other, this system is the lineal descendant of the philosophic speculations of the late Rig Veda and the Upanishads. Its basic textbook, by Bāda-rāyaṇa, composed possibly around the beginning of the Christian era, is called *Brahmasūtra*, (treatise on Brahma), *Vedāntasūtra*, *Uttaramīmāṃsāsūtra*, or *Sārirakāsūtra*, and consists of aphorisms in themselves unintelligible and meant to be accompanied by a commentary.

The celebrated Shankara (Śaṅkara), whose dates are uncertain but who was living around 800 A.D., is the author of the earliest surviving commentary on the *Brahmasūtra*. He taught unqualified monism (*advaitavāda*, doctrine of the non-second). His thinking starts with an examination of knowledge (*vidyā*; Sanskrit *vidyā*). This is of two sorts: one is absolute (*nirguṇa*, without qualification) or superior (*parā*), metaphysical, and gained only by the rarest of human beings. The other is relative, has qualifications (*saṁguṇa*), is inferior (*aparā*), illusory, suitable for the general run of people, who need concrete symbols. Shankara approaches the teaching of the Vedas in the light of higher knowledge. He refers to the passages of the Upanishads in which it is stated that Brahma (neuter), the supreme reality, is one only, without a second. This, other passages state, is identical with the individual reality. It cannot be described; all it is possible to say of it is that it is "not this, not this," that is, that it is nothing comprehensible to the senses and the mind. It can be known only by itself, that is, by the soul in the individual, which is the universal soul. This knowledge is the higher, unqualified knowledge, coming from experience (*anubhava*), where subject and object become one, leading the individual to the realization "I am Brahma" (*aham brahmāsmi*). The world as we know it phenomenally is qualified being, the absolute Brahma viewed by qualified knowledge or ignorance (*avidyā*, nonknowledge), where maya (Sanskrit *māyā*, illusion or artificial construction) operates. This is Shankara's treatment of nature (*prakṛiti*). Brahma is existence (*sat*), consciousness (*chit*; Sanskrit *cit*), bliss (*ānanda*; Sanskrit *ānanda*), completely self-sufficient. The universe is created from Brahma, yet is not Brahma; maya is unreal in contrast to the absolute reality of Brahma, but relatively real as a manifestation of the real Brahma.

Maya acts as an adjunct (*upādhi*) to Brahma to produce separate manifestations of soul and matter on separate levels of devotion. It produces a personal god called Brahmā (masculine), cosmic subtle elements, cosmic gross elements, cosmic subtle body, cosmic gross body, and the individual soul, with individual subtle elements, individual gross elements, individual subtle body, and individual gross body. The transmigrating soul is enveloped in five sheaths, which are associated with the grades of devotion. In progressing from the lowest to the highest stage, the individual soul passes back through the states of waking, dreaming sleep, and deep (dreamless) sleep, to the fourth state (*turiya*), which is capable of no description and constitutes realization of Brahma.

Men who live according to relative, qualified knowledge may, after death, go to the world of the fathers, or the world of the gods, or hell. But those who devote themselves to the higher,

unqualified knowledge aim to carry knowledge up from stage to stage until it is complete and through experience one knows that he is Brahma (neuter). To this end the accepted method is by yoga, with worship of God (the masculine Brahmā) in the first stages, but beyond that with progress dependent solely upon one's own efforts.

The most prominent of other Vedānta schools is that of Rāmānuja (fl. probably 12th century, in Kanchipuram) for whom God is personal, is identified with Vishnu, and has internal differences. Souls and matter both are real. The goal of man is union of his individual soul with God. The way to release is by devotion (*bhakti*) to Vishnu. Rāmānuja's system is characterized as qualified monism (*viśiṣṭādvaita*). Another school originating in south India is that of Madhva (probably 1197-1276), who was a dualist, recognizing the reality of God, souls, and matter. No two souls are alike. Still another school is that of Vallabha (1475?-1531), who called his view purified monism (*suddhādvaita*) and rejected the idea of maya. The way to salvation is union of the human soul with the highest God (Brahmā), who is personal as Krishna and is to be reached by devotion. Another important cult centering on Krishna was that of Chaitanya (1485-1533), in Bengal. Still another sect calling itself Vedānta is that of Nīlakaṇṭha (fl. 14th century), who identified God with Shiva. Nīlakaṇṭha considered his system monistic (*advaita*). The human soul is distinct from God, but its goal is to reach God, whereupon it diminishes, atom by atom, finally uniting with Him.

See also VEDĀNTA.

Medieval Cults.—Various sects, accentuating different religious motifs mentioned above, have developed in India since the time of the Purāṇas and have been cultivated in all parts of the subcontinent. Many center around Shiva or around Shaktism; others are devoted to Vishnu, especially in the form of Krishna. The Bhakti cults have been especially common since the 14th century. Such sects have generally tended to relax caste strictures among their adherents. Other sects have shown distinct Muslim influence. Of these one of the most important is that of Kabir (1440-1518), who came into contact with Sufism.

Reformed Hinduism.—In the 19th century religious reform movements arose partly from the impact of Western ideas upon Hinduism. Among the most prominent of these is the Brahmo (Brāhma) Samāj, a theistic, nonidolatrous movement using a congregational form of worship and favoring social reform, which was founded by Rām Mohun Rāi (Rām Mohan Roy, 1772/1774-1833). Later this movement was split; one part was led by Debendranath Tagore (1817-1905), father of the poet Rabindranath Tagore; the other, by Keshab Chandra Sen (1838-1884). Several other Samājas grew up after the example of the Brahmo Samāj.

Another important movement was the Ārya Samāj, founded by a Brahman named Dayānand Sarasvatī (1824-1883), who aimed to restore the religion and social institutions of the Vedas (which he understood in his own peculiar fashion), to protect cows, to restore India's glorious past, and so to check the advance of Islam and Christianity.

Still another was founded by Rāmakrishna Paramahansa (born Gadādhara Chatterji or Chāṭṭopādhyāya, 1834-1886), a Bengali Brahman

who taught that all religions lead to the same God and frequently experienced trance. His favorite disciple, Vivekānanda (born Narendranath Dutt, 1863–1902), spread the teachings of Ramakrishna in the West, first at the Parliament of Religions in Chicago in 1893, and later in Europe. The Ramakrishna Society is active in social reform in India and in preaching in several Western countries.

See also BRAHMO SAMAJ or BRAHMA SAMAJ; MISSIONARY MOVEMENTS—*Hindu Missions*.

Buddhism.—This religion is a heterodox Indian faith in that it does not recognize the authority of the Vedic scriptures. Its founder was Siddhārtha Gautama, commonly known by the honorific title of Buddha (the enlightened one), son of a petty ruler of a clan called Śākya (Śākya) at Kapilavastu in the northeastern part of the present Uttar Pradesh. Buddhist tradition places his death in 544 B.C., but modern scholarship sets his dates as 563–483 B.C. (alternatively, 558–478 B.C.). The Vedic religion was then dominated by a highly developed ritualism under the control of the hereditary Brahman priesthood, but the Buddha is constantly represented as saying that a man is a Brahman not by reason of birth in some family but because he has cultivated the intellectual and spiritual qualities of true religion.

The young prince Siddhārtha, after living for 29 years in his native city, left home to follow the religious quest. For 6 years he “wandered” from teacher to teacher and engaged in ascetic practices, all to no avail, but at last, while seated in meditation under a pipal tree near the Ganges at Gaya in the region then called Magadha, he attained enlightenment. After formulating his doctrine, he spent the rest of his life preaching it in nearby regions. Tradition says he preached his first sermon in a deer park at modern Sarnath, just outside Varanasi (Banaras). He founded an order of monks (vowed to avoid unchastity, theft, taking of life, and falsehood) and later admitted an order of nuns, and recognized a lay congregation. He died at the age of 80.

The Buddha's teachings, as preserved in the two main bodies of Buddhist scripture, are all considerably later than the Buddha and claim to represent the deliberations of various councils called to fix the scriptures. Especially important were one (the third) held in the 3d century B.C. under the patronage of the celebrated King Asoka and another under the patronage of King Kanishka, in the 1st or 2d century A.D., when the split between the Hinayāna (Lesser Vehicle) and Mahāyāna (Greater Vehicle) was recognized. The books were long transmitted orally. The Hinayāna canon, composed in Pali, is the older and is preserved in Ceylon (whence it went to Burma, Thailand, and Cambodia), where it was first put into written form in the 1st century A.D. (possibly 1st century B.C.). It is known as the *Tripiṭaka* (Sanskrit *Tripiṭaka*, Three Baskets) and is in three parts: (1) *Vinaya Piṭaka*, rules for monks; (2) *Sutta Piṭaka*, collection of discourses (*sutta*), that is, texts of psalms, stories, and other edifying material, in five sections; and (3) *Abhidhamma Piṭaka*, collection of works of the higher religion, bearing upon psychological questions. There is also a large body of uncanonical but highly valued texts and commentaries. The Mahāyāna division first used a Prakrit for its texts; later it used Sanskrit and had a canon in Sanskrit, also called the *Tripiṭaka*, of which

many works are preserved in India and Nepal but others exist only in Chinese versions.

In the Pali canon the Buddha's basic doctrine is considered to be expressed in his first sermon, called *Dhamma-cakka-ppavattana-sutta* (*Discourse on the Turning of the Wheel of the Law*). In this the Buddha accepts, without offering proof, the familiar Indian doctrine of the cycle of rebirth (*samsara*) and karma (retribution in future existences for one's deeds), the whole constituting a process that is painful. His message is that escape from this situation comes by avoiding the extremes of sensual indulgence and physical self-mortification and adopting the middle path. His basic theory is enunciated in the Four Noble Truths: (1) birth, old age, sickness, death, separation from what one wants, association with what one does not want—all are painful; (2) the pain rises from the thirst or desire for gratification of the passions and for existence or for termination of existence; (3) the cessation of pain comes from complete extinction of this desire; and (4) the way to extinguish the desire is to follow the Noble Eightfold Path of right views, right resolve, right speech, right action, right living, right effort, right mindfulness, right concentration. In various other discourses the Buddha is represented as refusing to discuss controversial metaphysical problems concerning the duration of the world, the identity of the self and the body, and the existence of the saint after death. He gives as the psychological basis of his doctrine a chain of causation or dependent origination (*Pali paṭiccasamuppāda*) of 12 members, which starts with ignorance and ends with suffering.

The Buddha placed a low value on the things of the world but did not deny their reality. Everything about the human being is a compound of the aggregates of being (*Pali khandha*), always in a state of change and therefore impermanent and painful. The only bliss is that of the immutable absolute, which the Buddha describes as the state of nirvana (*Pali nibbāna*, blowing out). The Buddha seems to have been vague on the subject of soul; the Pali texts in their received form specifically preach that there is no soul. The Buddha's law (*dhamma*; Sanskrit *dharma*) is all inclusive, governing nature, the individual, and metaphysics. It comes in time to be the object of worship. The Buddha himself is represented as saying that he finds no one to be his spiritual preceptor but the law, which resides in him. The Pali scriptures recognize four stages in the religious life; in the final stage one attains release from rebirth and suffering. The scriptures advocate meditation (*jhāna*; Sanskrit *dhyaṇa*) with the use of methods and stages more or less similar to those of yoga. Ethics is centered on ahimsa and *metta* (loving kindness).

The Hinayāna, as taught in the Theravāda school of the Pali canon, seems to have been dominant in India until about the beginning of the Christian era. After that the Mahāyāna school grew to prominence. The principal Mahāyāna doctrines, as distinguished from those of the Hinayāna, are (1) the doctrine of the Bodhisattvas (beings whose essence is true knowledge), who have attained the ability to become Buddhas but elect to remain in the universe so that they may make over their acquired merit to other beings; (2) the doctrine of the Buddhas, innumerable supernatural beings distributed throughout time and space; (3) the worship of images; and

(4) idealistic metaphysics. This form of Buddhism spread to central Asia, China, Tibet, Korea, Japan, and Java. The principal Indian Mahāyāna schools are (1) the Madhyamaka (Mādhyamika) school, prominent from about the 1st to the 5th century A.D., whose best-known teachers were Āśvaghoṣa (c. 100 A.D.) and Nāgārjuna (fl. 2d century A.D.); and (2) the Yogācāra (Vijñāna-vāda) school, prominent from about 500 to 1000 A.D., which was promulgated by the brothers Asaṅga and Vasubandhu, who lived in the 5th century.

Jainism.—Like Buddhism, Jainism is a heterodox movement, whose historical records start in Magadha in the 6th to 5th century B.C. It was promulgated then by Vardhamāna Mahāvira, the son of a petty ruler. The Jains put the date of his death at 527 B.C., but modern scholarship sets it at 468 B.C. (or 487 or 477 B.C.). Mahāvira left home at the age of 30 to follow the religious life, and in the thirteenth year of vigorous ascetism won supreme knowledge. From then until his death 30 years later he preached in and near Magadha. Though Mahāvira was the effective promoter of Jainism and established his own order, he seems to have been preceded 250 years earlier by a teacher called Pārshva (Pārśva) or Pārshvanātha (Pārśvanātha), who had established an order that required four vows of its followers: not to injure life, to be truthful, not to steal, to possess no property. The Jain texts tell of the union of this order with Mahāvira's during Mahāvira's lifetime. Mahāvira added a fifth vow for his monks, which was that of chastity. Pārshva had allowed his followers two garments, but Mahāvira, with a strict application of the prohibition against possessing property, permitted his monks none at all. Jain tradition indicates that the question of clothing for monks remained unsolved, and at about 300 B.C. the community split on the issue into two divisions: the Shvetāmbara or Svetāmbara (white clothed) and the Digambara (sky clothed, that is, naked). The division was formally recognized in 79 (or 82) A.D.

All Jains believe that Pārshva and Mahāvira were not the founders of the faith, but only the 23d and 24th in a series of teachers all of whom are called *tīrthāṅkara*, meaning "fordmaker" (across the ocean of existence) and "founder of a church," or Jina; modern scholarship considers the first 22 to be entirely mythical. The term "Jina" is an epithet like Buddha, and means "conqueror" (of the woes of life). From it is derived the religion's own term, "Jaina," a Sanskrit word meaning "follower [or doctrine] of the Jinas."

The Jain canon, which was written in the Ardhamagadhi language and transmitted by word of mouth, is said by the Digambaras to have been completely lost early in the 3d century B.C., at the time of a 12-year famine; the Shvetāmbaras claim that part of it was preserved. The oral tradition is said to have been put into writing in 454 A.D. The Digambaras live mostly in Mysore; the Shvetāmbaras, chiefly in Gujarat.

Jainism accepts the common Indian notions of rebirth and karma, with salvation consisting of escape from the round of existence (samsara). The universe experiences a continuous cycle of decline and improvement, descending and ascend-

ing like the hand moving around the face of a clock. We are now very near the bottom in the present cycle. The Jains acknowledge no universal God, though they have many lesser divinities who are bound in the round of rebirth. The world is eternal and consists of six substances: souls (jīva; Sanskrit *jīva*), right (dharma), wrong (adharma), space, time, and particles of matter. Souls are innumerable and are of two sorts: the perfected (siddha), who live in Īśatprāghbhāra at the summit of the universe, enjoying perfect happiness, incorporeal, invisible; and those bound by a subtle body of deeds (karma) to the present world, sullied by contact with nonsentient matter. Jainism carries the doctrine of ahimsa to an extreme not otherwise paralleled in Indian religions.

Souls in the round of rebirth are by Jains considered to be of various sorts, depending upon the number of senses and certain other qualities which they possess. First there are beings called *nigoda* with none of the senses; then (1) beings with one sense, which is touch, and with body, respiration, and an allotted span of life; these include stones, clods, minerals, water bodies, fire bodies, and vegetables growing in the ground, such as potatoes, carrots, and beets, which the strictest Jains will not eat; (2) beings with two senses (touch, taste) and having, in addition to the qualities possessed by one-sensed beings, the power of speech; these include worms; most Jains start the practice of ahimsa with this group; (3) beings with three senses (touch, taste, smell), which include ants, bugs, and moths; (4) beings with four senses (touch, taste, smell, sight), which include wasps, scorpions, and mosquitoes; and (5) beings with all five senses, which include hell dwellers, higher animals, human beings, and dwellers in the various heavens—some of this class have the quality of mind. Souls suffer bondage (*bandha*) to matter (*aḥjiva*) by karma, which is good (*puṇya*), that is, valuable in accomplishing the early stages of the advance toward salvation; or evil (*papā*), retarding the progress of souls. When karma is finally destroyed, the soul, free at last, attains salvation (moksha).

The Jain community consists mostly of merchants. In theory the Jains are opposed to caste, but in practice they maintain close relations with Vaishnava merchant castes and intermarry with them.

Sikhism.—Sikhism is a reformed sect, founded in the Punjab in the 15th century, which has drawn heavily upon the beliefs and practices of Islam. Its founder, Guru Nānak (1469–?1539), was familiar with Sufi mystic Islamic teachings; he preached monotheism, service to others, humility, self-restraint, and the mystical value of prayer. He abhorred idolatry, denied the validity of the Hindu caste system, setting up a common kitchen where all castes partook of the same food, and also opposed Muslim deistic theology. Nānak chose for God the designation Sat Nām (true name). He accepted the doctrines of karma and rebirth, of maya as a delusive force, and of guruship, that is, the magnification of the spiritual preceptor by the disciples (*sikha*, whence the name of the faith).

Guru Nānak was followed by nine other gurus. The new faith remained primarily a quietistic sect under the first five gurus, and acquired wealth. The fifth guru, Arjan (Arjun, guru 1581–1606) built (or rebuilt) a temple at Amritsar, which was demolished in 1761 by Ahmad Shah Durrani and

was restored by the Sikh ruler Ranjit Singh (1780–1839). This is the famous Golden Temple, and Amritsar is still the center of Sikh religious and political life. Arjan's successor, Har Gobind (guru 1606–1645), rejected wealth and ease and returned to the old simplicity, but adopted militarism and armed the community to resist both Muslim aggression and Hindu intolerance. The tenth and last guru, named Govind Singh (guru 1675–1708), in 1699 organized the military brotherhood into a band called the Khālsā, whose members went through an initiation ceremony, took names ending in Singh (lion), abjured wine, the narcotic hemp, and tobacco, forbade the cutting of the hair (*keś*), and imposed the carrying of a dagger (*kirpan*) and the wearing of drawers (*kach*), an iron bangle (*kartha*), and an iron comb (*kanga*). He was murdered in 1708. From the time of Har Gobind the Sikhs were in frequent conflict with the reigning Muslims. In the 19th century, Ranjit Singh established a Sikh kingdom in the Punjab, and Sikh political power extended from the Sutlej River into Afghanistan. After the Sikh Wars a final treaty was consummated with the British in 1849.

The Sikh scriptures consist of a book called Granth Sahib (Revered Book), which contains a great deal of prose and poetic material ascribed by Sikhs variously to Nānak, Kabir, and other teachers. It is regarded as the sole repository of religious authority and is held in veneration by all sects of Sikhism.

ISLAM

Islam in India has in one sense been in principle the same as Islam anywhere else, and in another sense it has necessarily acquired or produced special qualities relating to the unique Indian environment of those whose personal faith it has been. The dialectic between these two truths has constituted the character of Indian Islam. The endeavor here is to sketch the development of the peculiarly Indian understanding or expression by Muslims of their faith. It must be remembered throughout, however, that Muslims in India, confronted by the highly particular situations and problems that they met there from day to day and century to century, have had constantly available to them ideas, institutions, and personnel, including many of their leaders, from outside India in the wider Muslim world, as well as a cherished and graphic memory of the normative pre-Indian phase of their (Islamic) history.

Apart from the content of this ever-fresh supply of inspiration, its form too has been important. The sheer fact has often been consequential that the Muslim has lived in India dimly or vividly aware that he belongs, or belongs also, to a wider world transcending India in space and time and in his loyalty. All religious men have recognized that the immediate and tangible environment is subordinate to a higher reality; and India has honored this recognition and encouraged it. In the case of the Indo-Muslim, however, there has been a more complex, three-fold involvement: through Islam he has been related not only to the immediate environment and to God, but also to a partly alien tradition.

This states the problem from an Indian point

of view. Making the same point Islamically, one may observe that the environment in which the religion has had to relate its adherents to God has been a peculiarly complex and recalcitrant one. Most saliently, India has been the only major part of the Islamic world in which the community has continued to be a minority; only here has the religion proved of large-scale, sustained, sociocultural creativity where its adherents' task has been to live out their lives Islamically in a society of which most members have had other visions.

Elements of Indian Islam.—Two distinct and at times even opposed elements may be observed in the successful response of Islam to the situation described above. Neither is peculiar to or original with the community in India, yet both have developed there in special ways. They are power and Sufism (formal mysticism). The former is an aspect primarily of the political history of India. Suffice it here to touch upon the religious implications of the massive effectiveness of the Ghaznavid, Ghurid, Bahmani, and other dynasties in establishing Islamic rule in increasing parts of the subcontinent, culminating in the splendor and widespread might of the Mughuls (Moguls). The Qutb Minār in Delhi, symbol of conquest and power, may be seen as representing both the affirmative energy of the faithful in building up their dominion and the psychological comfort of feeling it secure. When six centuries later this power began to crumble, and in 1857 collapsed, repercussions in religious as in other aspects of the society's life were grave. In 1947, with outside rule withdrawing, the Pakistan movement may be interpreted in part as an assertion by many Muslims that Islamic life in the particular environment of India cannot be postulated without power.

The Sufi element in Indian Islam is at least equally important, more intimate, and perhaps more lasting. The faith was spread in India primarily by Sufis, and sustained primarily by them. The personal lives of individual Muslims have been Islamic largely in and through the structure and teaching of Sufi orders. In no major section of the Muslim world has Islam been Sufi oriented more than in India, and perhaps in none even equally so.

Of the many thousands of Sufi saints and leaders whose lives and interpretations at different times and in many places have expounded the faith and converted men to it or kept them responsive, many are nameless, and of course even of the others most must be so in so brief a survey as this. We may mention, however, a few of the exceptionally outstanding. In the early medieval period the two most usually noted are Mu'in-ud-Din Chishtī (1142–1236), who came from central Asia in 1192 and brought the Chishtī order, which he established in India; and Nizām-ud-Din Awliyā' (1238–1325). Their legends have inspired many millions of believers, and the celebration of their 'urs (festivals) at their tombs in Ajmer and Delhi, respectively, is still an occasion for pilgrimage for scores of thousands annually. Of the missionary Sufis in addition to Mu'in-ud-Din, south India traces its conversion primarily to such saints as Sayyid Nathar Shāh (969–1039); Muslim Bengal, to Makhdūm Jalāl-ud-Din Tabrizī (d. about 1244), followed by many others, including Mawlānā 'Aṭā' Muhaqqiq (d. about 1355). While the elite nourished their Sufism on Persian literature, in which the poetry

of Jalāl-ud-Dīn Rūmī (1207–1273) took pride of place, the common people found theirs sustained in the vernacular. The devotional life of the lower classes of the Punjab, for instance, has for long been expressed and fed by the poetry of such Sufis as Bullhe Shāh (c. 1680–c. 1758) and Wāris Shāh (fl. late 18th century), whose influence has been great with Hindus and Sikhs as well as Muslims; of Sind, by that of such Sufis as Shāh ‘Abd-ul-Laṭīf (c. 1689–c. 1752); of Bengal, by that of Sayyid Sulṭān (c. 1550–c. 1648), Sayyid al-Awwal (1607–1680), and others. Of the many Sufi orders represented in India, the most widespread and influential have been the Chishtīyah (from the 15th century), the Naqshbandīyah (from the 17th century), and, to a lesser extent, the Qādirīyah (from the 15th century) and in earlier times the Suhrawardīyah (13th century).

Concerning the content of Sufi thought and practice, Indian Islam had available to it virtually the whole diverse range of this aspect of the Islamic tradition, from orthodox to extremist, and had available also to a degree not yet carefully measured the influence of the somewhat similar Vedānta tradition of the surrounding Hindus. The first systematizer of Sufi thought in Islam, Hujwiri, came from central Asia to Lahore and died there (shortly before 1100). Of significant original thinkers in Islam, one may mention ‘Abd-ul-Quddūs Gangohī (d. about 1543) and, chiefly, Shaykh Ahmad Sirhindī (c. 1546–1624), who formulated a careful and eventually highly effective rejection of the pantheistic version of Sufism, insisting instead on an interpretation by which it could be, as it then increasingly was, subsumed under an Islam strictly within the bounds of the classical norms.

These norms, and especially the religious law (*sharī‘ah*), were brought with Islam’s advent into India, but only gradually and relatively late did they come to prevail and dominate. They were guarded and championed by the orthodox scholars, such as the influential ‘Abd al-Ḥaqq Muḥaddith of Delhi (1551–1642), and were institutionalized in the madrasah schools, of which one may mention chiefly Firangi Mahall, Lucknow, founded in 1693. Indian scholars cultivated and adorned these studies, though they did not basically develop them. A great compilation of law, the *Fatāwā-i ‘Alamgīrī*, is to be remarked under the Mughuls (17th century). Also worthy of note is the *Dars-i-Nizāmī*, a curriculum set up in the 18th century and still in force, for the formation of scholars, with a basis in *tafsīr* (commentary), *ḥadīth* (tradition), *kalām* (theology), and *fiqh* (law) from the classical Arabs but not without a certain flavoring of Sufi elements as well.

Relations with the Hindu Faith.—Islam’s first entry into India, on the west coast from Sind to Malabar (7th and 8th centuries), was of limited consequence compared with its later violent arrival (begun in 1001) through the Khyber Pass with the armies of Mahmud of Ghazni and his successors. This, with its vehement iconoclasm and exclusivism, was an overpowering onslaught on the religion of the Hindus such as India had never seen and has not yet quite forgotten or forgiven. The Sufis’ presentation of Islam, on the other hand, which presently gathered strength, won much of India’s heart and indeed in later centuries formally converted to the new community many millions of its inhabitants, chiefly no

doubt from the lowest castes. Although there is considerable room for investigation as to how far Islam and particularly Islamic Sufism of extra-Indian origin influenced the rise and spread of the Hindu Bhakti movement (11th to 16th centuries) and vice versa, in any case the fact is that relations between the two communities not only improved vastly but even reached a stage where syncretism seemed a possibility. This culminated under the Mughuls in the 16th and 17th centuries: politically in the reign of Emperor Akbar (1556–1605); culturally in such creations as the Taj Mahal (Tāj Maḥall, 1632–1653), miniature painting, and music; ideologically in Dārā Shikōh (1615–1659). The Urdu language might also be instanced. Some Muslims viewed the process as threatening the utter absorption of Islam within Hinduism and its eventual death. A reaction set in, expressed politically in Aurangzeb (r. 1658–1707) and intellectually in the movement stemming from Sirhindī. Politically, the reaction was either too late and too feeble, or else too vigorous and rigid—depending on one’s point of view; in any case, it was followed by failure, the disintegration of Mughul and presently all Muslim political and other power, and in the late 18th and early 19th centuries by social and intellectual demoralization and decline. Significant new Islamic developments since 1707 have been attempts to wrestle with that demoralization and decline, to rehabilitate the Muslim community in India both temporally and spiritually.

The foundation thinker for the new phase was Shāh Waliyullāh (1703–1762) of Delhi. His work was essentially purificationist and revivalist, aiming ideally at a restoration of a refurbished Sufism and a refurbished orthodoxy, in synthesis, and at a refurbished political power. This religious development was only beginning to work itself out, however, when it was enormously complicated by the new intrusion of the West. Although their ideological inspiration lived on, early 19th century uprisings (called Mujāhidin, or by their opponents Wahhābī), vigorously attempting to reinstate Muslim dominion and to erect a purified, truly Islamic society, were crushed. Indian power, whether Muslim, Hindu, or Sikh, was replaced for a time by British—not only politically but economically and culturally. In the second half of the 19th century and the early 20th century the community addressed itself chiefly to the new and perplexing relationship to the West. The gracious but potent leader here was the many-talented Sir Sayyid Ahmad Khān (1817–1898), and the phase is initially represented by the college that he founded in 1875, now Aligarh Muslim University. It was designed to make available to the Muslim community a modern (Western) education along with an Islamic training. The former produced an effective elite, but no synthesis was forthcoming. In the 20th century the brilliant and highly influential philosopher-poet Muḥammad Iqbāl (1876–1938) perhaps came closest to this with a scintillating eloquence affirming some reinvigorated elements from the Sufis along with some from modernity. Though his exuberance did not include a clear program, yet his work apparently reaffirmed the substance of the classical norms and actually heralded the next development, a reversion. For as had been the case in earlier centuries vis-à-vis the Hindus, but much more rapidly, overt conflict with the West gave way to rapprochement moves and then these to withdrawal.

When for various reasons Pakistan was proposed about 1940, most of those who responded religiously did so envisaging it as a solution to the problem of relationship to Hindus and as a revitalized reassertion of the community's normative tradition. The one vigorous religious formulation, that of Abū-l-A'lá Mawdūdī (1903–), is continuous with orthodoxy, likes power, and repudiates Sufism, Hinduism, and the West. Pakistan has found, however, that what was once the West has become international modernity. Islam must apparently live with and even through it or be downed.

The faith of the large section of the Muslim community living since 1947 in India has to cope with this problem and also with those of powerlessness and what is now more urgent than ever, the relationship with Hindus. In both Pakistan and postpartition India, Islam continues to face some of its deepest and most challenging problems.

Institute of Islamic Studies, McGill University.

CHRISTIANITY

The three major traditions of the Christian Church—the Eastern, the Roman Catholic, and the Protestant—are all present in India. The most ancient of these is the Eastern tradition. It now comprises four major groups known collectively as the Christians of St. Thomas, for they share the conviction that the church was established on the Malabar Coast through the missionary efforts of the Apostle Thomas. Near Madras is a hill where the saint is said to have been martyred. The early days of the St. Thomas Church are obscured in legend and find questionable support in the infirm geographical references of such works as the *Acts of St. Thomas*, which was probably written first in Syriac and later was translated into the Eastern tongues and into Latin. It can be stated with accuracy only that it is not impossible that the church was founded very early (even as early as its claims would indicate), and that its establishment and nurture were the work of immigrants to India from the eastern Syrian and Persian churches often termed Nestorian or, perhaps, of Catholics of the Chaldean Rite. The traditions and government of the church seem always to have been "foreign," and it is supposed that little concession was made to the Indian scene in thought or social practice, except that the members were accepted by surrounding Hindus as a group apart, which took its place rather high in the social structure of Hindu caste.

The Portuguese who came to Malabar early in the 16th century were welcomed by the St. Thomas Church. Gradually increasing control was exercised by Portuguese evangelists until, in the first half of the 17th century, a loose unity was made firm under Roman obedience. Those Malabar Christians of the Syrian Rite who have continued under Rome are known as Romo-Syrians. In 1653, however, about half of the St. Thomas Christians, feeling that their independence was in jeopardy, broke with Rome. Known as Jacobites

after Jacob Baradaeus, a 6th century Monophysite bishop, they have had a history marked by personal struggles for power. The continuing Jacobites are divided into two groups: those who recognize a patriarch; and the orthodox, who are ruled by a catholikos. The fourth major group of the St. Thomas Christians consists of the Mar Thoma Syrian Church, which seceded from the main body of the Jacobites in the mid-19th century. Evangelical in nature, this church forms an integral part of the cooperative Protestant movement and is in communion with the Church of South India. It sends colonizing groups as units to other parts of India, where they live a life in touch with the larger community.

Roman Catholicism.—From the beginning the Portuguese linked their quest for trade and colonies with evangelization, and the period of Roman Catholic missionary enterprise in India therefore opens with the arrival of Vasco da Gama at Calicut in 1498. Goa, which became the capital of the Portuguese territories in 1530, has remained the center of Roman Catholic activity in India. Because of its intimate links with secular colonial power, the church in Goa has been regarded as a European creation alien to the soil of India.

Among the first Roman Catholic priests who arrived in India early in the 16th century were Franciscans and Dominicans, of whom some were charged with the spiritual care of the Portuguese themselves and others were commissioned to act as missionaries. Then, in May 1542, less than two years after the establishment of the Society of Jesus, there arrived in Goa the first of two significant Jesuits. This was Francis Xavier (1506–1552), probably the greatest missionary that Europe has contributed to Asia. He was a scholar, a mystic, and a saint in both the Western and the Indian interpretations of the word. Despite little or no proficiency in any Indian tongue, he identified himself with the distressed masses of the people rather than with the luxury-loving Portuguese of the colony. The effects of his mission were widespread, for although he did not grasp the meaning of Indian culture, his saintliness, his obviously mystical nature, and his identification with the people won several hundred thousand converts to Christianity, largely from the depressed peoples of the western coastal areas of the peninsula. After his death in China in 1552, his body was brought to Goa, where it still remains.

While St. Francis' mission was identified with the sufferings and the life of renunciation of India, there was little appreciation of the religious philosophies which underlay Indian life, and Portuguese officialdom apparently received carte blanche to outlaw Hindu practices in the Goan area. With the study which the Jesuit Order fostered of language, religion, and literature, however, it was finally realized that here was a civilized people, inheritors of a great tradition, and that no missionary effort would succeed unless it took these things into account. Consequently, in 1606, a personality as colorful as Francis Xavier invaded the stronghold of south Indian Brahmanism, the city of Madurai. Father Roberto De Nobili (1577–1656), a brilliant linguist and a bold thinker, felt that the secret of the expansion of the church in India lay in the conversion of the Brahmans, the traditional leaders of Hindu religion. He studied Hinduism extensively and presented Christianity in a manner as little revolu-

tionary as possible. He himself took on the accouterments of the Hindu Brahman, and he sought to prove that pure Hinduism was much closer to Christianity than the prevailing popular practices. His sympathy for what he considered marginal social practices was successful in creating a church in Madurai, but much controversy was aroused because high-caste converts were permitted to continue the practices of caste, including that of untouchability. De Nobili was denounced by one of his followers as an impostor, in that he was believed to be a rishi (Sanskrit *ṛṣi*) from the West who had come to fulfill Vedic injunctions. This accusation played into the hands of those Christians who had criticized his work as indiscriminate syncretism, and he was forced to spend much time in defending himself to Rome. For over 40 years, De Nobili continued a type of mobile evangelism in the India he loved and in the Indian way of life he loved. His was a unique sympathy with the Indian people.

From Goa and from Madurai the successors of Francis Xavier and De Nobili established an extensive network of Roman Catholic mission stations. By the 1950's, the Indian church had its own cardinal as well as 19 archbishops, 51 bishops, and a large number of institutions.

Protestant Churches.—When representatives of Protestant countries of the West first reached India, they did not carry with them the same urge to Christian evangelism that was the inevitable accompaniment of Portuguese conquest. The Dutch were interested only in trade, and the English followed their commercial relations with political ambitions. In these ambitions there was no place for Christian propagandists, nor was there in the home countries themselves any real impulse to evangelization. The first instance of a sense of Christian mission from a Protestant source came from Denmark, which maintained a small trading post at Tranquebar in Madras. Here Protestant missions to India can be said to have originated. The first missionaries were the Germans Bartholomäus Ziegenbalg and Heinrich Plütschau, who reached Tranquebar in 1706. The greatest was Christian Friedrich Schwartz (1726-1798), who arrived there in 1750. His exemplary life gained him the confidence of all concerned, and he successfully negotiated diplomatic commissions between the British and their Muslim opponents in south India. With his death in 1798 the greatness of the Tranquebar mission declined.

English missionary enterprise received its first great impetus from William Carey (1761-1834), who dreamed at his cobbler's bench in England of far-off lands where he could exercise a Christian vocation. Eventually, through the Baptist Missionary Society, he was able to undertake a mission to India. Arriving in Calcutta in 1793, he was prevented by the British East India Company from establishing a mission in British-controlled territory. In 1799, however, with William Ward and Joshua Marshman, he established at the Danish settlement of Serampore a mission which emphasized education and the dissemination of literature through the printing of the Bible and other works in 36 languages.

After the East India Company lost its trading monopoly in 1813, it changed its policy regarding Christian missions. Hitherto only chaplains to the British community had been admitted. Now the London Missionary Society joined the pioneering Baptists, who were at last able to operate in British territory, and the Church of England with its

two organizations, the Society for Promoting Christian Knowledge and the Church Missionary Society. The Methodists also sent representatives to India, and the Scottish Missionary Society began its remarkable work in higher education—in Bombay under John Wilson (1829), in Calcutta under Alexander Duff (1830), and in Madras under John Anderson (1836). Americans were first represented by the American Board of Commissioners for Foreign Missions, founded in 1810 as a nondenominational body but shortly thereafter related to the Congregational Church.

Protestant Christianity in India had now entered its denominational phase, in which the various communions of the British Isles, the United States, and continental Europe sent missionaries to establish churches and humanitarian, educational, medical, and agricultural institutions. The new Christian churches not only made converts, but also influenced those who were to become India's courageous Hindu and Muslim reformers. In Bengal, Rām Mohun Rai (1772/1774-1833) created the Brahmo Samāj, a unitarian movement synthesizing the theistic elements of Hinduism with a social and ethical outlook inspired by Christianity. This and similar movements in Bombay challenged the lethargy and stagnation of contemporary Hinduism and led eventually to a period of renaissance and a new synthesis of far-reaching significance. The Muslim community began a movement of education and reconstruction extending from Sir Sayyid Ahmad Khān (1817-1898) to Muḥammad Iqbal (1876-1938).

The transition from multiple Protestant denominations came through the development of necessary cooperation and union. In 1914 the National Missionary Council was established. Renamed the National Christian Council, it is a consultative body which recognizes the integrity and sovereignty of the various denominations, but seeks through conferences and research to resolve questions of concern to all. It is in communication with the International Missionary Council and the World Council of Churches on questions involving Christianity in India and the world concerns of Indian churches. A further step was taken with the creation of such bodies as the South India United Church and the United Church of Northern India, which comprise Presbyterian, Reformed, and Congregational bodies in their respective areas. The most far-reaching movement toward unity was the inauguration of the Church of South India on Sept. 27, 1947. The result of years of consultation, this step makes possible the naturalization of the Christian Church on Indian soil.

The Indian church is concerned to find its place within the stream of Indian history without "foreignness." As a result, certain unique expressions of Christian life and thought have appeared, among them ashramas (Sanskrit *āśrama*), modeled on the traditional Hindu centers of the disciplined religious life. The unique characteristic of the Christian ashramas is that they reach out in terms of education or social service in a way which is not always present in the Hindu ashramas. They exhibit a new freshness of approach to some of the perennial problems of Indian life and thought. See also MISSIONARY MOVEMENTS—*Modern Christian Missions*; biographies of the leading missionaries.

Hartford Seminary Foundation.

14. LAW

Together with Pakistan, India became an independent nation on Aug. 15, 1947, under the terms of the Indian Independence Act (10 and 11 Geo. 6, Ch. 30). Its constitution, which was adopted by a Constituent Assembly on Nov. 26, 1949, and went into effect on Jan. 26, 1950, retained the laws already in force, subject first to the fundamental rights guaranteed therein, and second to subsequent legislation by the central legislature (Parliament) and the state legislatures within their special and concurrent spheres. The Indian Constitution is based on the Government of India Act of 1935, with elements derived from the United States Constitution. It is the supreme law of the republic, although it is more easily amended than the United States Constitution (by 1959 it had been amended seven times). The highest court, the Supreme Court, exercises a wider jurisdiction than the House of Lords in Great Britain, and it is not bound by its own decisions.

General Law.—Indian courts readily rely on English and, particularly in constitutional matters, American decisions. The common law of England is in force in the original civil jurisdictions of the high courts of Bombay, Madras, and Calcutta (which represent the old supreme courts) insofar as the law is not covered by statute or by the systems of personal law reserved for Hindus and Muslims. In similar matters, which rarely arise, all other jurisdictions apply "justice, equity, and good conscience." As the case may require, this means the general principles of the personal law that are most nearly applicable; the common and statute law of England, if it is not unsuitable to Indian conditions; or the judge's sense of propriety, founded upon a developed system of law.

While Parsis have their own statutory marriage, divorce, and succession laws, and Jews have their own customary matrimonial law, Armenians come under the general law. Christians (Armenians and others) are governed by the Indian Succession Act of 1925 (or by the Travancore Christian Succession Act of 1917), by the Indian Christian Marriage Act of 1872, and by the Indian Divorce Act of 1869, all of which approximate to obsolete English statutes. Since 1772 Hindus and Muslims have been privileged to use their own systems of law in family and religious matters, but the general law has impinged increasingly upon these systems in such fields as transfers of property, income tax, estate duty, and wealth tax. The Indian Constitution promised an Indian civil code, of which the so-called Hindu Code of 1955–1956 represented the first step. Similarly, it was hoped that the Special Marriage Act (Act 43 of 1954), which repealed and re-enacted with amendments Act 3 of 1872, would induce many Indian couples to register their religious marriages and so subject themselves and their issue to the general law in matters of matrimony and inheritance. Under that act all Indians who are over 21 years of age (males) or 18 years of age (females) and are not disqualified by a subsisting marriage may be married in a civil ceremony.

In general, Indian statutes dealing with finance, commerce, industry, welfare, and defense, as well as those relating to government ownership or supervision of the sources of wealth, are modeled on English precedents. Some, however, such as the Companies Act (Act 1 of 1956), diverge substantially in parts, and nowhere is Indian law a mere importation from the West.

After the constitution the fundamental law

still stems from the Anglo-Indian codes. Enacted in groups over the years, the codes were due to successive Indian law commissions working either in India or in England. In particular, they owed much to the skill of Sir John Romilly, Thomas Babington (later 1st Baron) Macaulay, Sir Henry James Sumner Maine, Sir James Fitzjames Stephen, and Whitley Stokes. These codes, which anticipated law reform in England, diverged from English law where the latter was too technical or imperfect. Their style reflected Utilitarian influence and, in places, French and American inspiration. Among the most famous of the codes are the Indian Penal Code of 1860, the Indian Succession Act of 1865, the Indian Contract Act of 1872, the Indian Trusts Act of 1882, the Transfer of Property Act of 1882, the Code of Civil Procedure of 1908, and the Code of Criminal Procedure of 1898 (often amended).

Some of the characteristic features of Indian law are the absence of jury trials; the fact that the profession is not divided into barristers and solicitors; the prevalence of compulsory registration of property transfers; the lack of registration of marriages and adoptions; the fact that testaments do not require probate; and the use of *benami* (Hindi *benāmī*) transactions, in which the real parties are concealed behind nominees.

Hindu Law.—Applicable to 85 per cent of the population of India, the system of Hindu law falls into three categories: (1) the *Dharmaśāstra*, the ancient Indian religious and civil law; (2) Anglo-Hindu law; and (3) modern Hindu law. Prior to 1827, Hindu criminal law was in force in Bombay Presidency, and it had been applied earlier in Banaras. Hindu law was the law of the land where the rulers were Hindus, and elsewhere it influenced the administration of justice by customary tribunals and even, in some of the Mughul (Mogul) jurisdictions, by courts sanctioned by authority. With the growth of British power, it was gradually superseded by statutory rules or, in the law of contracts, torts, and trusts, by rules which seemed consistent with English principles and were not repugnant to Hindu principles.

Dharmaśāstra.—The *Dharmaśāstra* covers the laws governing social, spiritual, civil, criminal, and constitutional matters—that is, the *varṇāśrama dharma*, or the duty (*dharma*) incumbent on persons according to their caste (*varṇa*; Sanskrit *varṇa*) and stage of life (*āśrama*; Sanskrit *āśrama*). Members of the numerous castes of India were classified in theory as either Brahmins (Sanskrit *Brāhmaṇa*), Kshatriyas (Sanskrit *Kṣatriya*), Vaisyas (Vaiśyas; Sanskrit *Vaiśya*), or Sudras (Shudras; Sanskrit *Sūdra*). The main duties of the Brahmins were to learn and teach the Vedas, to perform sacrifices, and to give and receive charity, while the chief duty of the Kshatriyas was to protect the people, that of the Vaisyas to engage in trade, and that of the Sudras to work for the three higher castes. These three castes were called twice born (*dvija*), because boys of these groups underwent an initiation ceremony which entitled them to study the Vedas and was considered a second birth. There were four *āśramas*: (1) that of the Vedic student (*brahmachārīn*), observing chastity and showing deference to his preceptor (*guru*); the householder (*grhastha*), a married man maintaining his family and propitiating his deceased ancestors with *śrāddha* ceremonies; the forest recluse (*vānaprastha*); and the ascetic (*sannyāsīn*), who had entirely abandoned the world. Most Indians are house-

holders nowadays, but there are some *brahmācārīn* and a few *saṃnyāsīn*.

In ancient India the king or his deputy maintained order and administered justice with the advice of Brahmans learned in *Dharmaśāstra*. The king himself was supposed to be trained in that science as well as in *Arthaśāstra*, the science of government. Most civil and social offenses and disputes were dealt with by tribunals (now known as panchayats) of a particular locality, caste, or profession, which made their decisions on the basis of custom. The ultimate sanction of the tribunals was excommunication.

There are six main sources of the *Dharmaśāstra*: (1) the Vedas, which provide scattered examples and indications of general principles; (2) the *Dharmasūtras* (thought to have been compiled before the 4th century B.C.), which are written either in prose or in a mixture of prose and verse and are attributed to such sages as Gotama (Gautama), Āpastamba, and Baudhāyana; (3) the *Smṛtis* (also known as *Dharmaśāstras* and dating from the 2d to the 7th century A.D. in one view, though according to others some specimens date from as early as the 4th century B.C.), which are written in verse and are attributed to Manu, Bṛhaspati (Brhaspati), Yājñavalkya, Nārada, Kātyāyana, Viṣṇu (Viṣṇu), and others; (4) commentaries on *Dharmasūtras* and *Smṛtis*, such as Medhātithi's commentary on Manu (c. 800 A.D.) and Vijñāneśvara's on Yājñavalkya (the celebrated *Mitākṣarā* text; early 12th century); (5) digests of *Dharmasūtra* and *Smṛti* texts, such as Lakṣmīdhara's *Kṛtyakalpataru* (c. 1050) and Mitrāmīśra's *Vīramitrodaya* (c. 1630); and (6) original treatises based on previous sources, among them Jīmūtavāhana's *Dāyabhāga* (early 12th century), Devaṇabhāṭṭa's *Smṛticandrikā* (early 13th century), Vācaspati-mīśra's *Vyavahāracintāmaṇi* (c. 1475), Nandapaṇḍita's *Dattaka Mīmāṃsā* (c. 1620), and Nilakaṇṭha's *Vyavahāramayūkha* (c. 1635). The epics and Purāṇas served as subsidiary sources of law. These sources were interpreted by jurists in terms of local usage and the requirements of jurisprudence. A distinction was made between what was morally desirable and what was legally essential.

Beginning about 1850 successive inroads were made into the practical application of the *Dharmaśāstra*, and by 1956 it survived only in the remoter Hindu communities and in religious contexts. The authority of the caste panchayats was reduced by the prohibition of excommunication in Baroda and then in Bombay State in 1949, and by attempts to eliminate the disabilities of the outcaste untouchables in state statutes and in the central government's Untouchability (Offences) Act (Act 22 of 1955).

Anglo-Hindu Law.—Anglo-Hindu law was based upon the *Dharmaśāstra* as reported to the British authorities up to 1864 by Indian experts. Between 1772 and 1955–1956 it was applied in India in matters of marriage, minority, adoption, succession, gifts and wills, the joint family, partition, maintenance, debts, religious endowments, and impartible estates. Apart from the joint family, only marginal matters were governed by it thereafter.

The opinions of the pandits (*paṇḍita*) were collected, compared with early translated texts, and systematized by Sir William Hay Macnaghten (1828–1829) and by his contemporary, Sir Thomas Strange. Their compilations wielded great influence, as did those of their successors, particu-

larly the textbooks of John D. Mayne and Sir Dinshah F. Mulla. Many of the ancient rules, such as those on disqualification from succession, were discarded as incapable of being administered under the British system. Others, such as the unfitness of an only son for adoption, were dropped as not intended from the first to be legally enforced, while a few were rejected as being against public policy. Gradually the laws were modified and amplified through principles of equity and through the enactment of laws of Western origin. Among statutory changes, the following were the most striking: from 1850 on, loss of caste ceased to involve loss of property rights in British India; widows have had the right to remarry since 1856; many disqualifications from succession were abolished in 1928; and the capacity to marry was broadened in 1946 and 1949.

Since there were many discrepancies between the sources, the courts frequently disagreed, and several schools of Hindu law were recognized. Nevertheless, the Privy Council in London supervised the growth of Anglo-Hindu law up to 1949 to fairly general satisfaction.

A custom, even that of a family, which was ancient, invariable, and not against public policy, might, if satisfactorily established, bypass Hindu law, creating a curious patchwork effect. Thus, divorce might be permitted, females might be excluded from succession, and a sister's son might be adopted. Moreover, before 1955–1956 some Indian states had special rules of their own. Subject to these reservations, the more striking features of the system with regard to marriage, adoption, the joint family, succession, and the like are described below.

Marriage was prohibited, but not necessarily void, between males under 18 and females under 15. It was void if between sapindas (Sanskrit *sapinda*), descendants from a common ancestor within five degrees inclusive on the mother's side or within seven degrees inclusive on the father's side; until 1949, if between *sagotras*, members of the same patrilineal family or persons having the family name in common; or if between members of different major castes. Marriage was indissoluble except in Bombay (from 1947) and Madras (from 1949), and the grounds on which a marriage might be annulled were in dispute. A man might have several wives concurrently. Either party could petition for the restitution of conjugal rights, and an ill-treated or deserted wife might sue for separate maintenance. A wife was regarded as half her husband's body, and a widow who remained chaste and unmarried was entitled to maintenance from her husband's estate.

While minority ended at 18, it was possible to adopt at an age as young as 15. Even a *de facto* guardian might validly alienate his ward's property for the latter's benefit or for legal necessity. In order that the male line might not be extinct, a man who had no sons might adopt one son (at a time) at his pleasure even if he were married, provided that the boy's mother would not have been prohibited to him for marriage, and that the boy was of the same caste and uninitiated (in the case of a Sudra, unmarried). Subject to conditions varying with the school of law, a widow might adopt to her husband (but not to herself as distinct from her husband), and the adoptee would be considered a posthumous legitimate son.

The joint family is the characteristic Hindu way of life and form of property ownership. It is patrilineal, and tends to be patriarchal. Accord-

ing to the *Mitākṣarā* school, males within four generations, inclusive, form by right of birth alone a coparcenary (joint heirship) in the ancestral property and its accretions, and the death of one increases the shares of the others by the operation of survivorship. (According to the *Dāyabhāga* school, a coparcenary interest is a defined share which passes by succession and not by survivorship.) The rights of survivorship end when the estate is partitioned or severed. Females may depend on the coparcenary property for their maintenance. Since 1863 a coparcener has had the right to appropriate what he has acquired through his own efforts, which then descends to his widow or other heirs, and by the Hindu Gains of Learning Act of 1930 all earnings not made directly by the employment of joint family funds are exempt from the claims of the other coparceners. Alienations by the "manager" of the family (usually the senior active male) bind all members if they are for necessity or for the benefit of the family (speculation is excluded). In the states of Bombay, Andhra Pradesh, Madras, Mysore, and Kerala a coparcener may freely sell or mortgage his undivided interest in the family property. From 1937 to 1956, under the Hindu Women's Rights to Property Act (Act 18 of 1937), the widow of a *Mitākṣarā* coparcener succeeded to her husband's place in the coparcenary, as well as taking a share equivalent to that of a son in his separate estate.

Succession to the estate of a male decedent was mainly agnatic (through males only), with heirs succeeding in a long order of priority, the nearer generally excluding the more remote. The widow, daughter, and daughter's sons followed in that order after the male issue, these last taking as a single heir. The act of 1937, however, improved the widow's position. The illegitimate sons of Sudras were allowed to take half a legitimate son's share, and in some cases they took a half or even all of an estate. A male inherited an absolute estate, but a female (with exceptions in Bombay) inherited a limited estate. This limited estate was better than a life estate in Anglo-American law, for a female could, in case of necessity, alienate her property absolutely. Her mismanagement could, however, be checked by the reversioners. With the consent of the nearest reversioner, she could, in practice, give a good title, but without such consent and without justification she could give a title that would endure only until she forfeited the estate by remarriage, surrendered it, or died. These restrictions applied equally to heiresses of females. Succession to females was complex, and differed according to the school of law and the mode of marriage of the deceased. Hermits were succeeded by their spiritual heirs and not by their kin, from whom their renunciation severed them in law.

To the extent of their interest in a *Mitākṣarā* joint family property, sons, grandsons, and great-grandsons are liable to pay the private debts of their male lineal ancestors, provided these debts are untainted by immorality or illegality. Under the principle of *damdupat* (believed by one high court to be unconstitutional), Hindu debtors cannot be obliged to pay at one time more interest than the amount of the principal.

Hindu deities own property and are represented by their managers (*shebait*s), whose powers are limited. The property of an orthodox religious college (*math*; Sanskrit *maṭha*) is managed by the head, usually called a *mahant*, who has wide powers of disposal subject to Hindu law

and the applicable Religious Trusts Act.

Modern Hindu Law.—The Hindu Marriage Act (Act 25 of 1955), the Hindu Minority and Guardianship Act (Act 32 of 1956), the Hindu Succession Act (Act 30 of 1956), and the Hindu Adoptions and Maintenance Act (Act 78 of 1956) made profound changes in the Hindu law applicable in India. Caste distinctions and differences of custom were nearly abolished in the eyes of the law. Marriage was made compulsorily monogamous. Subject to a waiting period of three years, divorce became available on such grounds as adultery, incurable insanity, leprosy, failure to comply with a decree of restitution for two years, and nonresumption of cohabitation for two years after a judicial separation. Judicial separation was made available for such reasons as desertion for two years, adultery, and cruelty. An annulment was made available for impotence.

Under the new laws guardians may make substantial alienations of their wards' property only with the consent of a court. A married man may adopt with his wife's consent. A boy may be adopted provided no male issue is alive, and a girl may be adopted if no daughter or son's daughter is alive. Moreover, a female may now adopt to herself alone. Where the sex of the adoptee differs from that of the adopter, at least 21 years' difference in age is prescribed. An orphan may be adopted with the court's consent.

Legal limited estates have been abolished. While succession to males and to females remains distinct, the two are more nearly similar than under traditional Hindu law. Many close relations share the estate of a male who dies intestate; thereafter all agnates, including the widows of a few close agnates, take a share, followed by all cognates on a basis of propinquity. In most cases, a *Mitākṣarā* coparcener's interest devolves by testamentary or intestate succession, not by survivorship. Illegitimate children no longer share in an estate, but their maintenance is properly secured. Maintenance rights have been regularized, and females may be liable to maintain their children and aged parents. Conversion from Hinduism, however, is still penalized in various ways (for example, rights to alimony are thereby lost).

Islamic Law.—The system used elsewhere in the Islamic world is in force in India in family and religious matters, including wills, *waqfs* (religious or charitable trusts), and pre-emption, subject to certain special features. To distinguish it from pure sharia (Arabic *sharī'ah*; canon law), it is often called Muslim or Anglo-Muslim law. Indian Muslims who are Sunnites follow the Hanafite school of law, while those who are Shī'ites are of the Ithnā 'Ashariyah or Ismā'īliyah schools. Several communities, including the Khojas, the Memons of Kutch, the Moplas (Malayalam *Māppila*), and some Bohras, formerly were governed by Hindu rules relating to the joint family and succession, but since the passage of the Shariat Act (Act 26 of 1937; amended by Act 16 of 1943) they have been governed by personal law in almost all important matters. Until 1861 and 1871, respectively, Islamic law, repeatedly modified, had also been in force in matters relating to crime and evidence. The sources of Anglo-Muslim law are not the Arabic texts as a whole, but only those generally acknowledged in India at about 1772, particularly the *Hidāya* and the *Fatāwā-i 'Ālamgiri*.

Western remedies and procedure have modified and supplemented the *sharī'ah*. Nevertheless, Is-

lamic law, which had a detailed literature from the beginning and belonged to a community that was slower to become Westernized than the Hindus, changed less than Hindu law under British administration. Moreover, case law is relatively less abundant than that of Hindu law. A striking conflict between Western and Islamic notions arose over the question of whether *waqfs* which provided only a remote or illusory benefit for strangers were valid, and the Privy Council's decision was reversed by the Mussalman Wakf Validating Act of 1913.

Important reforms of the marriage law, importing certain Malikite doctrines into India, were made in the Dissolution of Muslim Marriages Act (Act 8 of 1939), whereby a wife's rights to divorce were strengthened. The Muslim Wakfs Act (Act 29 of 1954) attempted to curtail the traditional freedom of the mutawallis (Arabic *mutawalli*; *waqf* trustees) by compelling them to register and to submit accounts. Muslims of education and means have availed themselves of the Special Marriage Act of 1954 in order to obtain freedom of testamentary disposition, but by the 1960's no general movement for reform of Islamic law had been noted in India.

15. GOVERNMENT

As one of the two countries into which the former British Indian Empire was divided on Aug. 15, 1947, India was first established as a dominion. It became a republic on Jan. 26, 1950, when a constitution, drawn up by an indirectly elected Constituent Assembly and adopted on Nov. 26, 1949, was formally inaugurated. The dominion government had previously "affirmed India's desire to continue her full membership of the Commonwealth of Nations and her acceptance of the King as the symbol of the free association of its independent member nations and, as such, the Head of the Commonwealth." This meant, in effect, that India continued to take its full share in intra-Commonwealth consultations regarding defense, finance, and other matters, and that its citizens did not become aliens in other Commonwealth countries. Its position differs from that of such older Commonwealth countries as Canada only in the republican form of government and in the absence of formal allegiance to King George VI, and later to Queen Elizabeth II, as the sovereign in whose name all governmental acts are performed.

Government Under the Constitution.—India is a sovereign democratic republic and a union of states. Although the structure of the government is federal, its spirit is unitary. The 15 states have very limited powers as compared with the states composing such other federal unions as the United States of America, Canada, and Australia. As in Canada, residual power rests expressly in the central government. The 9 territories and other centrally administered areas possess no states' rights.

Central Government.—*Executive:* All executive action is taken in the name of a president who is a ceremonial head of state acting on the advice of ministers responsible to a majority in the lower house of the central legislature. The president is a citizen over 35 years of age elected

for a five-year term; he may be re-elected. He is chosen by an electoral college formed of the elected members of both houses of the central legislature and of the elected members of the legislatures of the states. Each member of the college casts a large number of votes, the exact number being determined by an elaborate method of calculation based on census figures for the population of each state. The problem of succession in the event of the president's death or disability is handled by the provision for a special presidential election within six months thereafter. A vice president, elected at a joint sitting of both houses of the central legislature, presides over the upper house; he acts as president only during the short interval prior to the special election. The provisions concerning the cabinet introduce no novelty into the normally accepted conventions of the British cabinet system except for the provision of a professional attorney general, a portfolio obviously intended for an eminent lawyer whose tenure need not be affected by the vicissitudes of parliamentary politics.

Legislature: The central legislature consists of not more than 750 members, 500 in a lower house called the House of the People (Lok Sabha), and 250 in an upper house called the Council of States (Rajya Sabha). The 500 members of the House of the People are chosen by universal adult suffrage in such a way that there is not less than one member for every 750,000 persons, or more than one for every 500,000. The lower house is subject to dissolution in accordance with usual British practice; it is considered dissolved at the expiration of five years unless a proclamation of emergency is then in force. A cabinet minister may not hold his post more than six months without a seat in either house. He may speak, but not vote, in the house of which he is not a member. Of the 250 members of the upper house, 12 are eminent citizens appointed by the president because of their achievements in literature, art, science, and other fields. The other members are elected by the elected members of the lower houses of the state legislatures. The upper house is not subject to dissolution, but the terms of the members are so arranged that one third expire every two years. Provisions for a joint sitting of both houses obviate the possibility of legislative deadlock.

Judiciary: There is one national judiciary depending on appointment by the central government and protected by the usual safeguards which ensure the independence of judges in Great Britain. Salaries cannot be reduced. Removal cannot be effected except by an address voted by two thirds of both houses of the central legislature on the grounds of proved misbehavior or incapacity. The Supreme Court of seven justices is the guardian and interpreter of the constitution.

State Governments.—*Executive:* The governor is appointed by the president (that is, by the national cabinet), and his dependence on the central government is designed to be close and intimate. He is not merely a ceremonial head of state who acts always on the advice of a state cabinet responsible to a majority of the lower house of the state legislature. There is such a cabinet, but the governor has power to reserve bills for the president's consideration and is given authority to act in his discretion to a considerable extent.

Legislature: The state legislative structure may be bicameral or unicameral. All state legis-

latures, with the concurrence of a majority of the central legislature, may decide to change from a bicameral to a unicameral system or vice versa. The powers exclusively within the state legislative sphere are limited to such matters as education, public order, and police. State legislatures would, however, exercise in practice many of the powers listed on the concurrent list of powers shared with the central legislature, such as criminal and civil procedure, marriage and divorce, probate, trusts, and contracts.

Judiciary: There is no state judiciary.

Bill of Rights.—The list of fundamental rights enforceable in the courts is comprehensive and follows a United States rather than a British model. Its most significant provisions may be summarized as follows. No titles may be conferred. "No person shall be deprived of his life or personal liberty except according to procedure established by law." There are specific provisions against double jeopardy, *ex post facto* laws, and bearing witness against oneself. The prohibition of untouchability is absolute. No citizen on the grounds only of religion, race, caste, or sex may be denied access to stores, hotels, restaurants, and places of public entertainment or to any well, tank, road, or place of public resort supported wholly or in part by public funds. Freedom of worship and equality of treatment of all religions by the state are provided for, but the state may regulate any "economic, financial, political, or other secular activity" associated with religious practice and may effect social welfare or reform by such measures as the opening of Hindu religious institutions of a public character to any class or section of Hindus. Citizens may assemble peaceably and without arms. The right of freedom of speech is qualified by the government's right to make any law relating to a matter which "offends against decency or morality or which undermines the security of or tends to overthrow the state." The central legislature

may by law prescribe the circumstances under which, and the class or classes of cases in which, a person may be detained for a period longer than three months under any law providing for preventive detention.

Amendment.—The following matters are protected against hasty constitutional amendment: (1) the allocation of legislative powers between the central government and the states; (2) the representation of the states in the central legislature; and (3) the powers of the Supreme Court and the high courts. An amendment touching these matters must be ratified by one half of the states, as well as by the central legislature (a majority of the total membership in each house and a majority of at least two thirds of the members present and voting being necessary for ratification). Amendments touching other matters may be effected by the central legislature voting as described above.

Emergency Provisions.—Faced with war or domestic violence (actual or potential), the president may issue a proclamation of emergency which enters into force at once but must be laid before the central legislature within two months. The central legislature may by resolution of both houses extend the period of emergency beyond the period of two months. While such a proclamation is in force, the central government may exert any degree of control over state governments, and the guarantees to individuals in the bill of rights may be largely suspended. If, upon receiving a report from a state governor, the president is satisfied that the peace and tranquillity of a state are threatened, he may proclaim an emergency in such state, whereupon he may virtually take over the state, suspend the legislature, and legislate for the state through the central legislature. Such a regime, if ratified within two months by the central legislature and every six months thereafter, may continue for as long as three years.

Policy Toward Minorities.—The constitution retained for a 10-year period provisions for reserved seats in the lower houses of the legislatures for certain scheduled tribes and scheduled castes (it was extended in 1959 to 1970). Moreover, the scheduled tribes of primitive peoples, numbering approximately 10 million, retain their special status with adequate guarantees against exploitation. Authority was given to the president and the governors to nominate to the lower houses of the central and state legislatures a few representatives of the Anglo-Indian (Eurasian) community. Not more than two such representatives may sit in the central legislature.

Provisions Concerning Language.—According to Article 343, "the official language of the Union shall be Hindi in Devanagari script" but "... for a period of fifteen years from the commencement of this Constitution, the English language shall continue to be used for all the official purposes of the Union for which it was being used immediately before such commencement." In 1963, Parliament extended the use of English as an official language for an additional 10-year period, to 1975.

The Constitution in Operation.—The Indian constitutional system underwent surprisingly little change during its first years. It is remarkable that the drastic changes that took place in the political map—the rapid integration of the former princely India and the former British India, culminating in a redrawing of state boundaries not

Prime Minister Nehru with his daughter and grandson.

Kulwant Roy

foreseen in 1950 and the incorporation of foreign enclaves—necessitated only five amendments to the constitution. The other nine amendments adopted by 1963 generally strengthened the hand of the central government. Apart from reapportionment as a consequence of the 1951 census, extension of special provisions for minority seats, adjustment of the border with Pakistan, a slight change in the procedure for election of the president and vice president, and provision for legislatures and councils of ministers in certain territories, these amendments related primarily to two matters: the facilitation of social reform, especially land reform; and the conferment of broader powers to restrict freedom of speech and writing which prejudices friendly relations with foreign states, public order, decency, and morality. The adding of several key commodities to the concurrent legislative list and the fixing of a procedure for settling disputes over compensation for landlords have enabled the central government both to prevent hoarding and to remove obstacles which formerly stood in the way of land reform projects planned in several states.

The selection of a respected elder statesman, Dr. Rajendra Prasad, as India's first president, has ensured that the presidency would remain, as the authors of the constitution intended, above partisan politics. When, in 1962, his successor was elected, the choice fell on the vice president, Dr. Sarvepalli Radhakrishnan, one of India's most distinguished philosophers. He in turn was succeeded in the vice presidency by a noted educator, Dr. Zahir Hussain.

In more than one instance since 1950 the central government has acted promptly to assume charge of the government of a state which was in the throes of political confusion and unable to form a stable ministry. Nothing has occurred since 1950 to strengthen the position of the states within the Union. The States Reorganization Act of 1956, involving a reduction of the number of states and the virtual disappearance of the princes from Indian public life, has increased the power and prestige of the central government.

Political Development Under the Constitution.—The course of political events, the general elections of 1951–1952, 1957, and 1962, and the evolution of India's political parties, as described in *19. History Since 1947*, throw much light on the nature of Indian politics. What chiefly strikes the foreign observer is that the republic's political system is basically a one-party system dominated by Pandit Jawaharlal Nehru, the surviving personality from the period of the struggle for independence, who symbolizes for the masses the achievement of nationhood and freedom. Yet the Congress Party is not the party of one man, nor is India a one-party authoritarian or police state rather than a parliamentary democracy. The three general elections have given a surprising demonstration of the workability of universal adult suffrage among a preponderantly illiterate population through the use of pictorial party symbols and a well-organized system of polling supervision. The politically conscious and largely English-knowing intelligentsia from which the republic's rulers are drawn has shown an ability to preserve the independence of the judiciary, the integrity of the civil administration, and the subordination of the military to the civil authority—three great bulwarks against the transformation of a parliamentary democracy into a dictatorship.

The continuance of the so-called one-party system in the central government is due primarily to two factors—one the survival of most of the Congress leaders who were the chief architects of independence, and the other the importance of personal leadership in Indian political life. Both factors are to some extent the consequence of the fact that in India, as in most Asian countries, the politically conscious form a tiny minority, most of whom are acquainted with each other. Indian political life before independence was characterized by much fluidity as between political groupings: politicians thought nothing of identifying themselves with more than one political following at the same time. Moreover, secessions from and returns to political groups were frequent, and were ways of expressing political discontent and of changing the character of a group or faction by ostracizing it until it yielded to criticism. During such periods of secession a popular political personality often offered himself as an independent and built up a personal following. Since independence this has been true especially in contests for seats in state legislatures, where the number of independent nonparty candidates has been truly astonishing. Hence a basically one-party system in India does not necessarily imply a monolithic system. The failure of a two-party system of the traditional British type to evolve during the first decades of Indian independence is a natural consequence of India's previous political history. The occurrence of political deadlocks in certain states, such as Andhra Pradesh, in which no party or group of parties could govern, and the success of non-democratic parties in winning control of a state government, as the Indian Communist Party did in Kerala from 1957 to 1959, indicate the dangers facing democratic government in India. Stable nonauthoritarian government does not require a two-party system, but it does require the continuance of a preponderance of agreement among the stronger Indian political groups as to the fundamental nature of the "sovereign democratic republic" established under the constitution on Jan. 26, 1950. 16. PREHISTORY

Early Indus Civilization.—The earliest known civilization in the Indian subcontinent dates back to the 3d and 2d millennia B.C. It has been found at a large number of sites uncovered by archaeological exploration in the area drained by the Indus River system as well as at other sites to the west and to the southeast. This area seems then to have received or conserved more moisture than in modern times, and harbored such marsh and jungle animals as the rhinoceros, buffalo, tiger, and elephant, all of which are frequently represented in art, while the camel is scarcely indicated. Preceding or contemporary with the Indus civilization were a number of relatively primitive cultures, differentiated mostly by pottery types and known as Nal, Amri, Zhob, Togau, Quetta, and Kulli (Kulli-Mehi), which have been discovered west of the Indus as far as Kerman Province, Iran.

The characteristic Indus civilization was first discovered at Harappa in the Punjab in what is now West Pakistan, and hence is called the Ha-

rappa civilization. Much the most advanced of all the ancient Indus cultures, it endured for the longest time and is the best explored. It has been found as far north as Rupar on the Sutlej River, in the former states of Bikaner and Bahawalpur, and at a profusion of sites in Sind, mostly west of the Indus, while a southern outpost appears at Rangpur in Kathiawar. The civilization contained two large cities—Harappa and Mohenjo-daro, in northern Sind—each more than three miles in circumference; some smaller cities, of which one, Chanhudaro in central Sind, has been well explored; and a number of villages. It was in contact with civilizations in Mesopotamia and the Iranian highland as early as 2350 B.C., but must have been in existence before then, and it continued at least as late as the 17th century B.C. and possibly later.

The architecture of the Harappa civilization was of brick, and the cities were planned, the principal streets being carefully oriented. Harappa and Mohenjo-daro each had a walled citadel and may have been the capital of a large kingdom. Both they and Chanhudaro possessed elaborate public drainage systems. The houses were usually separate and equipped with baths, their drainage connecting with the public system. The people used copper and bronze extensively, wore cotton clothing, and had jewelry of shell, pottery, gold, and beads of various kinds, of which the most noteworthy were made of etched carnelian. Both cubical and tabular dice have been recovered. The civilization had a system of writing, which appears abundantly in short inscriptions on steatite seals and occasionally on pottery and metal but has not been successfully deciphered. The economic, social, and political structure is unknown, but the cities were commercial and there were wide variations of wealth. While weapons and missiles have been found, we can reconstruct very little of the Harappan art of war. There are surviving stone and bronze sculptures, pottery figurines, many carved seals, and a vast amount of painted pottery. The thick-walled, red, wheel-made Harappa pottery has a characteristic black painted decoration of animal, foliage, and geometric motifs. A number of motifs in Harappan art are paralleled in contemporary western Asia, and others reappear 1,000 years or more later in historic India, but the connecting links have not been found. What people owned this civilization is not known, but it is frequently suggested that they were Dravidian.

Following the Harappa civilization came the Jhukar civilization, with towns sometimes built upon Harappan remains but with less competent architecture. This civilization had no writing. It is distinguished by its own type of polychrome painted pottery. While we do not know how either it or the Harappa civilization before it came to an end, suspicion has been cast upon the relatively uncultured Aryan invaders of the 2d millennium B.C. as its destroyers. At an undetermined interval after the Jhukar civilization a primitive culture known as Jhangar, otherwise unidentified, existed in the lower Indus Valley. It is characterized by a gray, incised pottery.

Early Vedic Civilization.—The next epoch in the history of civilization in the subcontinent is that of the penetration and early spread of the people who composed the Rig Veda (*Rgveda*) and other early Vedic works for use in their religious ritual. All our information about them is literary, drawn from their texts without supple-

ment from material remains. The Vedic people spoke an early form of Sanskrit, called themselves *Arya* (noble), and were closely related in language and other phases of culture to the Iranians, forming with them a subgroup of the Indo-Europeans termed Indo-Iranian or Aryan. They are generally considered to have entered the subcontinent through the passes of the northwest frontier at around 1500 to 1200 B.C.

The Aryans were nomadic, and the cow was their unit of value, but they also raised crops, especially barley. They had fortified settlements, used metals, wore helmets and body armor, and may have introduced the horse into the subcontinent, though some horse bones have been found in late Harappa remains. Their most prized weapon was the bow. They gambled with *vibhidaka* nuts in place of dice, and had an intoxicating drink called *sura* (Sanskrit *surā*).

Aryan society was patriarchal and was divided into (1) Aryans, who were subdivided into the Brahmins (*Brāhmaṇa*) or spiritual aristocracy, the Kshatriyas (*Kṣatriya*) or Rajanyas (*Rājanya*), rulers and warriors, and the Vaisyas (*Vaiśya*; Sanskrit *Vaiśya*) or commons; and (2) non-Aryans called Sudras (Shudras; Sanskrit *Sūdra*) or serfs. The Aryans were organized in clans or tribes, each ruled by a king or *raja* (Sanskrit *rājan*). There was an assembly of the free folk. The Rig Veda contains references to wars between tribes, but little history can be reconstructed.

The land of the Rig Veda is the eastern Punjab; the Jumna and Ganges rivers and the region between them are barely known to that work, and there is no information about the means and stages by which the Aryans progressed from the Punjab to the east and south. By about 1000 B.C., however, they seem to have advanced into the plains of northern India, in modern Uttar Pradesh, and by about 800 B.C. to have reached Bihar and the western part of Bengal. They may also then have got to the central part of India, coming down from the Gangetic Valley, and in the west to have descended the Indus, crossed Kutch, and arrived in Gujarat.

Formation of Historic Indian Civilization.—The first blending of the diverse elements which formed historic traditional Indian civilization took place from the 7th to the 3d century B.C. For this period archaeological exploration has revealed much information on topography, cultural developments, and social conditions, which supplements the data in late Vedic literature and the Buddhist and Jain traditions. Aryan civilization, as modified by contact with non-Aryan culture, established itself in north India, and there are presumptive reasons for thinking that a Dravidian civilization existed simultaneously in south India. In these same centuries the Brahmanic philosophic speculations embodied in the Upanishads (*Upaniṣad*) and the two heterodox faiths of Buddhism and Jainism, which developed in north India, spread abroad. The Achaemenid dynasty of Persia came into contact with India in the 6th century B.C., and in the inscriptions of its kings we get our first dated documents of Indian history.

17. HISTORY: 6TH CENTURY B.C.—1707

Pre-Gupta India, 6th Century B.C.—4th Century A.D.—While it is not possible to present a definite picture of the political condition of India before the 6th century B.C., it is known that there were then no less than 16 important states in northern India. Some of these states, like those of the Lichchavis, Sakyas (Śākyas), and Mallas, were republics, while others, such as Kosala (modern Oudh), Avanti (Malwa), Vatsa (the region round Allahabad), and Magadha (southern Bihar) were monarchies. Under a succession of able rulers like Bimbisara (r. about 543–491 B.C.) and his son Ajatasatru (r. about 491–459 B.C.), Magadha gradually became the most powerful. In the mid-4th century B.C., a Sudra named Mahapadma Nanda usurped its throne. By a series of brilliant military campaigns he made himself master of an empire extending from the Brahmaputra River on the east to the Beas River on the west.

The region west of the Beas, which was still divided into a number of small states, fell an easy victim to foreign invaders. Darius I, the Achaemenid king of Persia, conquered part of it toward the close of the 6th century B.C., and Alexander the Great led his victorious army as far as the Beas in 327–325 B.C. Alexander died in 323 B.C., and the Greek garrisons he left behind were driven from the Punjab by Chandragupta of the Maurya clan (r. about 321–297 B.C.), who also defeated the Nanda ruler of Magadha. Chandragupta thus founded an empire which embraced nearly all of northern India and probably included lands farther south. Its capital was Pataliputra (modern Patna). Seleucus I Nicator, the able general who took possession of Alexander's eastern dominions, led an expedition in 311 B.C. to recover the lost territories in the Punjab. It failed, however, and about 304 B.C. the two rulers concluded a treaty whereby, in exchange for 500 elephants, Seleucus ceded to Chandragupta nearly all of the region comprised in modern Afghanistan and Baluchistan. Not much is known about Chandragupta's son and successor Bindusara (r. about 297–274 B.C.), but the latter's son Asoka (Ashoka; Sanskrit Aśoka) was the greatest ruler of ancient India.

Reign of Asoka, c. 274–237 B.C.—Aśoka is the first Indian ruler of whose life and reign we possess fairly full and accurate information from inscriptions, more than 30 of which have been found engraved on rocks and pillars from Mysore in the south to Afghanistan in the northwest. He had inherited an empire which extended to the Hindu Kush in the northwest, and included almost all of modern India and Pakistan with the exception of the petty Tamil kingdoms in the south and Kalinga (modern Orissa) on the east coast. In the ninth year of his reign he led an expedition against Kalinga, which was conquered after a sanguinary war. According to Asoka's own account, "150,000 were captured, 100,000 were slain, and many times as many died" in the course of the campaign.

The sight of this bloodshed changed the tenor of Asoka's life. Converted to Buddhism with its doctrine of ahimsa (Sanskrit *ahimsā*, noninjury of living creatures), he forswore war and, in-

stead, devoted himself and the resources of his empire to the propagation of the precepts and doctrines taught by the Buddha. He organized a network of missions which spread Buddhism not only throughout the subcontinent of India, but also to Ceylon and probably to Southeast Asia as well. His missionaries are known also to have visited the rulers of the Hellenistic principalities of western Asia, northern Africa, and eastern Europe, five of whom are named specifically in his records. It was due mainly to Asoka's efforts that Buddhism, which had been merely a local Indian sect, gradually developed into a world religion. While his earthly empire perished long ago, his name is honored today by Buddhists in many lands.

Asoka's inscriptions testify to his high conception of royal duties and to his humanitarian principles. He was untiring in his efforts to help his subjects both materially and spiritually, and he not only preached but practiced religious toleration. Moreover, he made notable contributions to the development of Indian architecture and art.

India After the Death of Asoka.—With Asoka's death the Maurya Empire began to disintegrate. Very little is known about the next seven kings of the dynasty, the last of whom was killed about 184 B.C. by his commander in chief, Pushyamitra, who founded a new dynasty called the Sunga (Sunga, 184–72 B.C.). By this time the northwestern frontier was again exposed to foreign invasions.

The empire which Seleucus had founded from the eastern portion of Alexander's conquests included Bactria, beyond the Hindu Kush, which revolted about 250 B.C. under its governor, Diodotus I. At the beginning of the 2d century B.C., the Greek rulers of the new kingdom of Bactria began to invade India from the northwest. Some of them—Demetrius I, Apollodotus I, Menander—advanced far into the interior, and although Pushyamitra succeeded in repelling invasions of central and eastern India, more than 20 Greek princelings are known to have ruled over small states in the Punjab and Afghanistan.

Other foreigners soon followed the Greek example. The Parthians, the Sakas (Śakas), and lastly the Kushanas (Kuşāṇas), a branch of the Yuechi (Yüeh-chih), all entered India from the northwest and fought one another. While the rule of the Greeks and the Parthians was extinguished by the 1st century A.D. and that of the Sakas was confined to Gujarat, Kanishka (Kanishka), the most powerful of the Kushana kings (fl. 1st or 2d century A.D.), ruled over an empire that extended as far as Banaras in the east and included large parts of Afghanistan and central Asia.

Meanwhile, the rest of northern India was divided into a large number of independent monarchies and republics. Kharavela, ruler of Kalinga (fl. 2d or 1st century B.C.), invaded northern India several times, and may have fought the Greeks. Another powerful kingdom was founded in the Deccan, probably in the 2d century B.C., by Simuka, a member of the Andhra Satavahana (Śātavāhana) family. Its capital was Pratihasthana (modern Paithan), on the Godavari River. The Satavahanas ruled for four and a half centuries—longer than any other dynasty of ancient India. Gautamiputra Satakarni, the most powerful king of the family (fl. early 2d century A.D.), claimed in inscriptions to have defeated the Sakas,

Yavanas (Greeks), and Pahlavas (Parthians). The Satavahanas, who thus defended the south against foreign intruders, were also great patrons of art and literature, and their memory is cherished in the legends of King Salivahana (a form of Satavahana).

Farther south, beyond the line of the Krishna (Kistna) and Tungabhadra rivers, flourished the principalities of the Cheras, Cholas, and Pandyas (Pāṇḍya), who occupied respectively the western, eastern, and southern parts of the Tamil country. Their constant wars, resulting in the occasional supremacy of one principality over the two others, are described in Tamil literature. Many legends have clustered around such powerful kings as Karikala (Karikkal) Chola and Nedunjeliyan Pandya. Some time before the 4th century, A.D., however, a new dynasty, the Pallava, conquered the region around Kanchi (modern Kanchipuram or Conjeeveram) and within a short time established its supremacy in the Tamil area.

Gupta Period, 4th to 6th Century A.D.—A new dynasty, called the Gupta, rose to power early in the 4th century A.D. and reunited a large part of India. Chandragupta I (r. 320–?330), originally the ruler of a petty principality in southern Bihar or northern Bengal, conquered a number of neighboring states and established a powerful kingdom with its capital at Pataliputra, the old imperial city of the Mauryas. Assuming imperial titles, he founded an era beginning in 320 A.D., which was probably the date of his accession. It was his son and successor, Samudragupta (r. about 330–375/380), who brought the dynasty to the height of its greatness. Samudragupta, the hero of 100 battles, has been called the Napoleon of India. By annexing the states of a number of kings whom he defeated in northern India, he extended the territory under Gupta administration to the Jumna and Chambal rivers on the west and to the Narbada River on the south. In addition, several states beyond these boundaries acknowledged his suzerainty. Samudragupta also undertook a military expedition to southern India, advancing along the east coast as far as the Pallava kingdom of Kanchi. While he defeated about a dozen south Indian kings, they were permitted to retain their thrones, presumably as vassals of the Gupta Empire.

Chandragupta II (r. 375/380–c. 413), the son and successor of Samudragupta, defeated the Sakas and annexed Gujarat, thus removing the last traces of foreign rule in India. He also probably led his victorious army beyond the Indus River as far as Balkh and imposed his suzerainty over the Kushana principalities in the northwest. His son, Kumaragupta I (r. about 413–455), maintained intact the vast empire, which now extended from the Bay of Bengal to the Arabian Sea. Toward the close of his reign the Huns invaded India from the northwest, but the crown prince, Skandagupta, inflicted such a crushing defeat on them that for nearly half a century India was saved from their raids. Skandagupta himself had a short reign, and his death, which occurred about 467, seems to have been followed by a struggle for succession, from which Budhagupta emerged victorious and ruled until nearly the end of the century. Budhagupta's death was a signal for internal dissension, and the Huns reappeared on the northwestern frontier. Between about 500 and 528 two Hun chieftains, Toramana and Mihirakula, advanced as far as Malwa, and although a Gupta king, Narasimha-

gupta, and a feudatory chieftain, Yasodharman, both claim to have defeated Mihirakula, the Huns could not be dislodged from India. By about 530 A.D., Yasodharman established his authority over the entire empire, but by the mid-6th century both he and the Gupta Empire had been brought to a common ruin.

The Gupta period is known as India's golden or classical age. It was during this period that art, literature, and science reached the highest levels, setting a standard which was alike the ideal and the despair of Indians in later times. The Chinese pilgrim Fa-hsien, who was in Gupta dominions from 405 to 411, has left us his impressions of the empire at its height.

Post-Gupta Period, 6th to 8th Century.—The Gupta Empire perished, but the memory of its greatness survived. While northern India was again divided into a number of independent principalities during the next two centuries, able kings attempted repeatedly to re-establish political unity. Some were temporarily successful, but the empires they founded did not survive their deaths. The first of them was Sasanka, king of Bengal at the beginning of the 7th century, who led his victorious army as far as Kanauj in the west and the Ganjam District of Orissa in the south. The next was Harsha (Harshavardhana, r. 606–?647) of Thanesar and Kanauj, who was able to establish his authority over a large part of northern India, although he was defeated (c. 620) by Pulakesin II, the Chalukya king of the Deccan. While Harsha's empire also ended with his death, he is better known than the others because the Chinese pilgrim Hsüan-tsang traveled in India for 15 years during Harsha's reign and has left a graphic account of his activities. Half a century later another ruler of Kanauj, Yasovarman (r. about 700–740), made extensive conquests but was defeated by Lalitaditya, king of Kashmir (r. 724–760), who also established an empire which perished after his death.

Meanwhile, momentous developments were taking place in the Middle East. The Prophet Mohammed, who died in 632 A.D., had not only established a new religion, Islam, but had made the Arabs a militant nation. By 650 they had overrun the Persian Empire, Syria, and Egypt and had advanced as far as the Oxus River (Amu Darya). While they naturally cast longing eyes on India, their early efforts at conquest were not successful. Between 637 and 644 they sent three naval expeditions to the subcontinent, and between 650 and 700 several military expeditions were dispatched by land to Kabul, Zabul, and Sind. Finally, after more than half a century, they conquered Sind in 712. From this base the Arabs tried to reach Kashmir and Kanauj, but they were checked by Lalitaditya and Yasovarman. Some time between 724 and 738, Junayd, the Arab governor of Sind, advanced as far as Malwa and Gujarat, but his forces were repulsed by the Pratihara ruler Nagabhata I and the Chalukya governor of Gujarat.

Northern India, 8th to 10th Century.—*Rivalry of the Pratiharas, Palas, and Rashtrakutas.*—The Pratihara (Pratihāra) ruler Nagabhata I (r. about 730–760) who defeated the Arabs was a member of the Gurjara tribe and the founder of a dynasty which became very powerful in Rajasthan toward the close of the 8th century. In their efforts to build an empire in northern India the Pratiharas found a formidable rival in the Palas (Pāla), who had established

their power over Bengal and Bihar. Since the death of Sasanka, Bengal had been conquered by a succession of foreign rulers and had fallen into a state of political disintegration. There was no central authority, and local chieftains constantly fought one another. At last, roused to a sense of duty by the miserable condition of Bengal, these chieftains, by a heroic resolve unique in Indian history, surrendered their power to one of their number, Gopala, whom they elected in about 750. Gopala reunited Bengal, whose prosperity he restored, and became the founder of a long line of kings whose names ended in *pāla* (protector), and which is consequently known as the Pala dynasty.

At the same time a new power arose in the Deccan. The Satavahanas, who had ruled this region until the early part of the 3d century, were replaced in the 4th and 5th centuries by the Vakatakas (Vākātaka), and they in turn were succeeded by the Chalukyas (Chālūkyā), who established a powerful kingdom, with Badami as its capital, in about the mid-6th century. The greatest king of this dynasty was Pulakesin II (r. 609/610–642), who extended his domains as far as Mysore in the south and Malwa and Gujarat in the north, and defeated Harsha and the Pallava king Mahendravarman I (r. 600–630). The next Pallava ruler, Narasimhavarman (r. 630–668), retaliated by defeating Pulakesin in 642 and by occupying his kingdom for 13 years. Although Pulakesin's son recovered the kingdom, the Chalukyas were overthrown in about 753 by the Rashtrakutas (Rāstrakūṭa). The Rashtrakutas not only defeated the Pallavas and the Western Gangas of Mysore, but two of their kings, Dhruva (r. 780–793) and his son Govinda III (r. 793–815), led successful expeditions against their northern neighbors.

Thus toward the end of the 8th century there was a triangular struggle for supremacy in northern India among the Gurjara Pratiharas of Malwa and Rajputana, the Palas of Bengal and Bihar, and the Rashtrakutas of the Deccan. The Pratihara kings Vatsaraja (r. about 775–800) and his son Nagabhata II (r. about 800–833) won great victories over the Palas, but in turn suffered serious reverses at the hands, respectively, of the two Rashtrakuta kings, Dhruva and Govinda III. Dharmapala (r. about 770–810), the son and successor of Gopala of Bengal, also submitted to Govinda, who advanced as far as the Himalaya but soon returned to the Deccan because of internal difficulties in his kingdom. Taking advantage of this situation, Dharmapala led a victorious army as far as Kangra in the northwest. He was consecrated emperor at Kanauj in the presence of rulers whom he had subjugated, and is referred to in later literature as lord of Uttara-patha (northern India). His son and successor, Devapala (r. 810–854), claimed supremacy over all of northern India from the Himalaya to the Vindhya Range.

After the death of Devapala the Gurjara Pratiharas once more came to the fore. Mihira Pratihara (called Bhoja, r. about 836–890), the greatest ruler of the dynasty, after initial failures succeeded in establishing his authority over most of northern India. His son Mahendrapala (r. about 890–910) penetrated the heart of Bengal itself. The Pratihara Empire, with its capital at Kanauj, now extended from northern Bengal to the Kathiawar peninsula, and a single imperial writ ran from the Arabian Sea almost to the Bay of Bengal. The word *pratihāra* means "door-

keeper," and the Pratihara kings justified their name by successfully barring the gates against the advance of Muslims from Sind and Multan.

Decline of Indian Power and the Muslim Invasions.—By the mid-10th century the Pratihara Empire showed signs of decline. One by one its feudatory chieftains declared their independence, and soon northern India was once more divided into a large number of principalities. Among the more prominent were those of the Chandellas in Bundelkhand, the Kalachuris in the vicinity of Jubbulpore, the Paramaras (Paramāra) or Pawars in Malwa, the Chaulukyas in Gujarat, the Chahamanas (Chāhamāna) or Chauhans in Jai-pur and Ajmer, and the Tomaras in the region around Delhi. They were the progenitors of the Rajput (Rājput) families who distinguished themselves in medieval times, but they were not as yet known by that generic name. Other contemporary powers included the old Pala kingdom of Bengal and Bihar; and the Hindu Shahiya (Shāhiyā) kingdom in western Punjab and Afghanistan, which had been founded by the Brahman minister of the last king of a dynasty which traced its descent from Kanishka.

Northern India had thus reverted to the condition that invariably followed the downfall of an empire. Nevertheless, the idea of restoring political unity persisted, and such powerful individual rulers as the Chandella kings Yasovarman (r. about 930–950) and Dhanga (r. about 950–1002) and the Paramara king Vakpati II (known as Munja; r. about 972–995) attempted to establish empires. Left to themselves, these powers might again have achieved imperial unity, but that was not to be. The small Turkish Muslim kingdom of Ghazni proved too formidable an enemy.

The Hindu Shahiya king of Afghanistan and western Punjab, Jayapala (Jaipal), who was resolved to crush the new power threatening India, succeeded in organizing a confederacy for the purpose, but it was defeated near Jalalabad (988) by Subuktigin (Sabuktigin), the ruler of Ghazni. After Subuktigin died in 997, Jayapala made a second attempt to drive out the Ghaznavids, but he was defeated and captured near Peshawar by Subuktigin's son Mahmud. Mahmud of Ghazni, who was the greatest general of his time, established his authority in Balkh, Herat, and Khurasan and invaded India at least 12 and possibly 17 times. He defeated a second confederacy of Indian rulers organized by Jayapala's son Anandapala (Anandpal). His raids, which were made almost every year in the cold season, were generally directed against the rich Indian temples, which he desecrated and plundered. Those Hindus who refused to embrace Islam were ruthlessly massacred. Then, at the advent of spring, Mahmud returned to Ghazni with a rich booty and innumerable slaves, including artisans to build and decorate his capital. He annexed the Punjab to his kingdom, and although the rest of northern India remained independent, its resources in men and goods were depleted.

The Deccan and Southern India, 10th to 13th Century.—The region south of the Vindhya Range, which was not affected by the invasion of Mahmud, pursued its normal course of development. In the Deccan the Rashtrakutas were supplanted by the Chalukyas, who claimed descent from the earlier royal family of the same name but ruled from a different capital, Kalyani. They are therefore known as the Later Chalukyas or the Chalukyas of Kalyani. In the far south the

Pallavas had been displaced in the 9th century by the Cholas of Tanjore, who soon became the dominant power of the region. Under two able rulers, Rajaraja I the Great (r. 985–1014) and his son Rajendra Chola I (r. 1014–1044), the Cholas defeated the Later Chalukyas, the Pandyas, and the Cheras; sent victorious armies along the Bay of Bengal as far north as the Ganges River; and conquered Ceylon and the Laccadive and Maldiv Islands. Their most remarkable achievement was a successful naval expedition against the Sailendra (Sailendra) rulers of the Malay Peninsula, Sumatra, and Java. The Cholas distinguished themselves in many other ways. They introduced an efficient administrative system based on local democratic self-government and an extensive land survey. In addition, the Chola kings were magnificent builders, and the Brihadiśvara Temple still stands in Tanjore as a monument to their greatness.

By the mid-13th century the Pandyas of Madurai had broken the power of the Cholas and had become the dominant power in southern India. Meanwhile, in about 1190, the Later Chalukyas of the Deccan also were ruined. They were supplanted by three new powers, the Hoysalas (Hoyśāla) of Mysore, the Yadavas (Yādava) of Deogiri (Devagiri, modern Daulatabad), and the Kakatiyas (Kākatīya) of Warangal. These three powers and the Pandyas constantly fought one another, oblivious of the catastrophe that had overtaken northern India.

Northern India, 11th and 12th Centuries.

—The political situation in northern India in the 11th and 12th centuries changed in only three respects: (1) the Hindu Shahiya kingdom now formed part of the kingdom of Ghazni; (2) the Gahadavalas (Gāhaḍavāla) or Gaharwars replaced the Pratiharas, who had been extinguished by Mahmud; and (3) the Pala dynasty of Bengal was supplanted in the 12th century by the Senas. With the other principalities of northern India, the Senas and the Gahadavalas pursued the old policy of struggling among themselves for supremacy. There were some powerful individual rulers, but they made no concerted effort to drive the Ghaznavids from the Punjab and so prevent the conquest of the rest of northern India. This could have been accomplished easily when the kings of Ghazni were defeated by the rulers of the neighboring Muslim kingdom of Ghor or Ghur, and the Ghurids sacked Ghazni itself (1151) and forced its rulers to take shelter in the Punjab. The Chahamanas king Prithviraja (r. 1178–1192), then the most powerful Indian ruler, ignored these opportunities and, instead, fought other Indian princes. Even when Muhammad Ghuri, who had ascended the throne of Ghazni in 1173, captured the last Ghaznavid ruler and made himself master of the Punjab (1186), Prithviraja was indifferent. It was not until Muhammad Ghuri began to raid his frontiers that the Chahamanas ruler realized his grave danger. He thereupon organized a great confederacy of Indian rulers and, in the First Battle of Tarain (Taraori, 1191), inflicted a major defeat on Muhammad Ghuri. The Ghurid forces were routed, and their king, severely wounded, returned to Ghazni. Nevertheless, Prithviraja took no advantage of this opportunity and made no attempt to conquer the Punjab. A year later, Muhammad Ghuri returned with a picked army and met Prithviraja at the same battlefield of Tarain. While Prithviraja fought bravely, he fell a victim to a clever ruse and was defeated and

killed. The Hindu army was routed.

The second Battle of Tarain must be regarded as one of the decisive battles of the world, for it paved the way for the Muslim conquest of India. Muhammad Ghuri followed up his victory by other successful campaigns, the most notable being the defeat inflicted in 1193 on the Gahadavala king Jayachandra (Jaichand), by which Muslim territory was extended to the borders of Bengal. Muhammad Ghuri spent most of his time at Ghazni, leaving the task of completing the conquest of northern India to his lieutenant, Qutb-ud-Din Aibak. In 1206, while returning from one of his occasional campaigns in India, he was assassinated on the bank of the Indus. Henceforth, Qutb-ud-Din ruled as an independent king in India. Assuming the title of sultan, he fixed his capital at Delhi.

Delhi Sultanate, 1206–1526.—*Slave Dynasty, 1206–1290.*—Qutb-ud-Din, the first sultan of Delhi (r. 1206–1210) put down Hindu rebellions and conquered some new territory. His son-in-law Iltutmish (Altamsh, r. 1211–1236), who succeeded to the throne after a brief interval, successfully maintained the new sultanate by repelling a Mongol invasion from the northwest, crushing Hindu resistance, and adding to his territory. His death provoked a struggle for the succession, during which an aristocracy of 40 Turks who had begun their lives as slaves (as had Qutb-ud-Din and Iltutmish themselves) wielded actual power. A daughter of Iltutmish, Raziyya (r. 1236–1240), fell a victim to a court conspiracy, and the dissension continued until one of the 40, Ghiyas-ud-Din Balban, took control, first as deputy of the nominal ruler, Iltutmish's son Nasir-ud-Din Mahmud (r. 1246–1266), and then as his successor and sultan *de jure* (r. 1266–1287). Ghiyas-ud-Din restored order by suppressing rebellions and by curbing the power of the slave aristocracy. Wisely he consolidated Muslim dominions instead of conquering new lands, and he secured the northwestern frontier against the Mongols by building a chain of strongly garrisoned forts. He enhanced the prestige of the court and made Muslim rule in India strong and stable. His successor, Kaiqubad, a worthless debauchee, was killed by one of the Khalji (Khalji) nobles, whose leader ascended the throne in 1290 under the title of Jalal-ud-Din Firuz Shah.

Khalji Dynasty, 1290–1320.—Jalal-ud-Din Khalji (r. 1290–1296) was treacherously murdered by his nephew and son-in-law, Ala-ud-Din (r. 1296–1316), who proved to be one of the greatest Muslim rulers of India. Ala-ud-Din conquered all of the Hindu kingdoms in northern India which had hitherto defied the Muslims—those of the Paramaras of Malwa; the Rajputs of Mewar; and the Vaghelas (Vāghela) of Gujarat, who had replaced the Chalukyas—and incorporated their territories in the Delhi Sultanate. A new Mongol invasion caused him to reorganize the northwestern defenses. Once he had completed the conquest of northern India, Ala-ud-Din sent several expeditions under his general Malik Kafur to the Deccan and southern India. Kafur defeated the Yadavas of Deogiri, the Kakatiyas of Warangal, the Hoysalas of Mysore, and the Pandyas of Madurai, and the victorious banner of Islam was carried to the southernmost point of the peninsula. While Ala-ud-Din annexed the Yadava kingdom, whose rulers had repeatedly rebelled against him, he was satisfied to exact tribute from the other three principalities. He organized a powerful

standing army and replaced the former system of military feudalism by a strong, centralized government. Despite his great victories and successful administration, Ala-ud-Din was an illiterate, vain, and cruel man. He declared himself a second Alexander and even aspired to be the prophet of a new religion. Excesses ruined his health, and in 1320, four years after his death, his dynasty was overthrown by Ghiyas-ud-Din Tughluq.

Tughluq Dynasty, 1320–1414.—Ghiyas-ud-Din, who died after a reign of five years, is generally believed to have been murdered by his son Muhammad Tughluq (r. 1325–1351). The most contradictory personality among the Muslim rulers of India, Muhammad was an excellent scholar, a fine writer, an eloquent orator, and a great general. But he was also extremely cruel, and he exacted for all crimes, great or small, the death penalty, which was sometimes inflicted with a revolting barbarity. Muhammad adopted a number of visionary projects, such as the transfer of the capital from Delhi to Deogir (renamed Daulatabad) in 1327, the substitution of token copper and brass currency for gold, and the attempted conquest of Khurasan. All of them were costly failures which brought great misery to the people. In certain areas bad conditions were worsened by inordinate increases in taxation. The revolts which broke out were generally put down with savage cruelty, but some of them were successful. By the time Muhammad died, all of India south of the Vindhya Range had shaken off the suzerainty of Delhi, and two powerful new kingdoms had arisen: the Muslim Bahmani kingdom in the Deccan and the Hindu kingdom of Vijayanagar in the south. In addition, Bengal had declared its independence.

Firuz Tughluq (r. 1351–1388), who succeeded Muhammad, made two unsuccessful attempts to recover Bengal but did not try to regain the southern provinces. His long reign was distinguished by the foundation of a number of cities; the digging of irrigation canals, some of which still exist; and the construction of parks, hospitals, bridges, and other public works. The prosperity of the sultanate was restored, and an effective system of administration was instituted.

Firuz was succeeded by incapable rulers whose reigns were marred by interminable wars of succession, of which the provincial governors took advantage to become *de facto* independent rulers. At this juncture, India was invaded by Tamerlane (Timur), who carried fire and sword as far as Delhi in 1398–1399. He gave the death blow to the Turkish Empire in India, which was now divided into such independent principalities as Bengal, Jaunpur, Malwa, Khandesh, Gujarat, and the Hindu states of Mewar and Orissa in the north, the Muslim Bahmani kingdom in the Deccan, and the Hindu kingdom of Vijayanagar in the south. The history of these independent states, some of which produced remarkably able rulers, really constitutes the history of India during the 15th and the first half of the 16th century.

Sayyid and Lodi Dynasties, 1414–1526.—What remained of the Delhi Sultanate (the Jumna Valley and the Punjab) was acquired in 1414 by Khizr Khan Sayyid, whom Timur had appointed governor of his Indian possessions. The Sayyid dynasty was overthrown by an Afghan chieftain, Bahlul Lodi, in 1451. The Lodi rulers showed some vigor and, after a 30-year struggle, recovered Jaunpur. Nevertheless, internal dissension, caused by a dispute between Ibrahim Lodi

(r. 1517–1526) and his unruly Afghan nobles, sapped the strength of the sultanate, and on the invitation of some disaffected nobles, Babur (Baber, real name Zahir-ud-Din Muhammad), ruler of Kabul, invaded India. After defeating Ibrahim Lodi in the First Battle of Panipat (1526), he took possession of Delhi and Agra.

Mughul Empire, 1526–1707.—The dynasty founded by Babur is known as the Mughul (Mogul), for although he was descended on his father's side from Tamerlane, his mother belonged to the family of the Mongol conqueror Genghis Khan. Shortly after his victory at Panipat, Babur faced the opposition of the brave Rajputs led by Rana Sanga of Mewar, but he obtained another brilliant victory at the Battle of Khanua (1527). In both of these battles he enjoyed the advantage of artillery, with which his opponents were unacquainted. Before he could consolidate his dominions, however, he died (1530) and was succeeded by his son Humayun.

The new king could not cope with Sher Shah, an Afghan chieftain of humble birth who had made himself powerful by sheer ability. Sher Shah seized Humayun's throne and brought nearly all of northern India under his control. His death after a brief reign (1540–1545) enabled Humayun, who had taken refuge in Persia, to return to India and to recover his kingdom in 1555. He died within a year, however, and the Afghans again seized Delhi. Under the able guidance of Bairam Khan, Humayun's son Akbar, then only 14 years old, defeated the Afghans in the Second Battle of Panipat (1556) and finally established Mughul supremacy in northern India.

Akbar was the greatest Mughul emperor. During his long reign (1556–1605) he conquered Malwa, Gujarat, Gondwana, Bengal, Kashmir, Khandesh, Berar, and other provinces and won over the Rajput states by a policy of conciliation and matrimonial alliances. (The premier Rajput chieftain, Rana Pratap Singh of Mewar, refused to submit, however, and waged a lifelong war against Akbar.) Akbar had many great qualities. Not only was he an excellent general and a sound administrator, but he displayed religious tolerance far in advance of his time. He assembled at his court representatives of different religions, whose discourses he enjoyed. By abolishing the *jizyah* (poll tax imposed on Hindus) and appointing Hindus to high civil and military office, Akbar won their hearts, and the Hindu Rajputs became the strongest pillars of the Mughul Empire.

Jahangir (r. 1605–1627), the son and successor of Akbar, married the beautiful and talented Nur Jahan after ascending the throne, and he left affairs of state mostly in her hands. Mewar was finally conquered and Kangra was captured during his reign, but the strong fort of Kandahar fell to the Persians (1625).

Jahangir's son Shah Jahan (r. 1628–1658) was an able general and a great patron of the arts. The kingdom of Ahmadnagar was finally annexed to the Mughul Empire during his reign, and Bijapur and Golconda, the last of the five states into which the old Bahmani kingdom had been divided, acknowledged Mughul suzerainty. Shah Jahan's reign, which is usually regarded as the golden period of Mughul rule in India, is memorable for its magnificence. Besides the famous Taj Mahal (Tāj Mahall) and the Moti Masjid (Pearl Mosque) at Agra, the emperor decorated his new capital at Delhi (named after him Shah-

jahanabad) with the Red Fort, which contained the celebrated Diwān-i-ʿĀm, the Diwān-i-Khāss, and the Peacock Throne. The last days of the reign of Shah Jahan were embittered by a struggle among his four sons for succession to the throne. The third son, Aurangzeb, after defeating his brothers, confined the old emperor in the fort of Agra and ascended the throne in 1658. Shah Jahan died a captive eight years later.

Aurangzeb (r. 1658–1707) was a good general and an able ruler, but his bigotry and suspicious nature ruined the empire. Since he did not trust anyone, he never secured the confidence or goodwill of others. Reversing Akbar's policy of toleration, he reimposed the *jizyah* on the Hindus, destroyed their temples and idols, dismissed them from public service, and discriminated against them in trade and other matters. These measures alienated the Rajputs, with whom Aurangzeb was forced to wage a long and bitter war. Meanwhile, a new power developed in the south under Shivaji (Śivājī), who presented himself as the champion of Hinduism against Islam and brought into being a new nation, that of the Marathas. Aurangzeb made a strenuous effort to crush Shivaji, but despite initial successes he failed in the end. In 1674, Shivaji succeeded in founding an independent Hindu kingdom in Maharashtra.

Shivaji died in 1680, and almost immediately thereafter Aurangzeb concluded a treaty with the Rajput ruler of Mewar and proceeded to the Deccan to consolidate Mughul supremacy there. He remained in the Deccan for nearly 26 years. During this period he finally conquered Bijapur and Golconda and advanced (1690) as far as Tanjore and Trichinopoly (now Tiruchirappalli). Although the Mughul Empire thus reached its greatest extent under Aurangzeb, he failed to destroy Maratha power. He conquered the Maratha forts one after another, and the enemy seemingly disappeared, but as soon as he left an area the Marathas recaptured the forts, harassed the Mughul army by guerrilla tactics, and even pillaged the imperial camp. Aurangzeb faced a national rising which his undoubted military talents and the vast resources of the empire could not subdue. At last, wearied by the hopeless task, the old emperor returned to Ahmadnagar, where he died in 1707. His protracted wars in the Deccan and the tactics of the Marathas had exhausted the imperial treasury and demoralized the Mughul army and nobility; his long absence in the south far from his capital had disorganized the administration of the empire; and the destruction of Bijapur and Golconda had facilitated the growth of the Maratha Empire. While Aurangzeb seemingly left the Mughul Empire at the height of its power, in reality he brought it to ruin.

18. HISTORY: 1707–1947

The 240 years between the death of the last great Mughul (Mogul) emperor, Aurangzeb (r. 1658–1707), and the inauguration of independent governments in India and Pakistan saw the European intrusion into the Indian subcontinent culminate in complete foreign conquest and then give way to a reassertion of power by Indian leaders determined to shape their countrymen's

own destiny. These years may be conveniently divided into three periods. In the first, 1707–1815, European commercial penetration was supplemented by a military struggle between the British and French (assisted by their Indian allies) which left Britain unchallenged as mistress of India; in the second, 1815–1885, Britain built its Indian Empire; in the third, 1885–1947, a nationalist movement developed to whose leaders British power was finally surrendered, but not until many changes had been made in the Victorian bureaucratic regime and all efforts to preserve Indian political unity had failed.

BRITISH CONQUEST (1707–1815)

European Commercial Penetration.—The progressive disintegration of Mughul central authority which characterized the early decades of the 18th century gave rise to struggles between Indian princes to which the European powers, already firmly entrenched in trading posts called factories, could not be indifferent. Doubtless, increased European commercial activity tending to turn the more important factories into fortified enclaves outside Indian control played its part in weakening the Mughul Empire. Nevertheless, the directors of East India trading enterprises in Europe did not embark willingly and deliberately upon the course of embroilment in Indian disputes from which the building of a British empire in India was to follow. Their chief concern was trade, at this period the purchase of India goods—that is, chiefly cotton and silk hand-woven cloth, raw silk, pepper, salt-peter, and sundry drugs—with the proceeds of cargoes of silver, base metals, and woollens exported from Europe. They hardly realized the extent to which, in developing their trading organizations, they had laid the foundation for the subjection of vast regions of Asia to European control. These were no ordinary commercial enterprises: they had most of the attributes of governments, though possessing influence and wealth rather than territory. Indeed, the oldest of them, which in the course of the 16th century had set the pattern for all the rest, was and remained a government, for the Portuguese crown never granted monopoly rights in East India trading to a company of its subjects but managed the business itself, sending out its trading fleets, manning its commercial outposts with its servants and their Eurasian progeny, defending them with Eurasian and other mercenaries, and making the Portuguese language the *lingua franca* of the whole East from the Cape of Good Hope to Canton.

The Dutch, English, French, and Danes, who conducted their East India trading through companies chartered by their respective governments, followed the Portuguese pattern and perfected it. By the early 18th century nearly the whole littoral of southern Asia and its adjacent islands from the Arabian to the China seas was dotted with European trading factories of one kind or another—at one port, as at Mocha, these were floating factories, the ships of the East India companies lying offshore at the coffee-selling season; at another, as at Bombay, a whole island with a magnificent harbor was held in full European sovereignty, a haven of peace and security to which any Asian trader could bring his capital and skill; or, as at Surat, the European companies maintained factories side by side under agreements with the local authorities.

In all these factories lived tiny groups of Europeans, all but submerged by the teeming Asian life around them, six months from home by sea, preoccupied by their struggles with Asia's "corrupting sun" and their hopes of surviving to return with a respectable fortune. In their employers' eyes their primary business was writing—that is, compiling the ledgers and drafting the correspondence always in duplicate and often in the triplicate and quadruplicate which distance from Amsterdam, London, Paris, Copenhagen, and Lisbon entailed. They would not have been at their posts at all, however, had they not been permitted to trade *within* Asia on their own account. In the profits of such trade lay their main hope of achieving financial independence.

In his private capacity an enterprising and ambitious servant of a European East India company like the American-born Elihu Yale, governor of Madras from 1687 to 1692, had his own commercial establishment with his own ledgers and letter books recording his own commercial ventures in the Indian seas, his own Eurasian or Indian clerks, and often a "country ship" or two of his own manned by lascar crews under European captains and mates of his own choosing. In his public capacity, whether a governor of a great factory and fortress like Madras or a young factor or writer on his way up the ladder of preferment, such a man was serving a large and often complex trading organization with its headquarters in Europe. At this period the greater of these East India companies, the Dutch and the English, administered large fleets both outward and homeward bound in each annual trading season, managed resources equal to those of many an Asian prince, coined money both on their own behalf and on that of others, carried on a vast correspondence within Asia as well as to and from Europe by land as well as by sea, and conducted diplomatic negotiations with local political authorities almost entirely on their own responsibility. As piracy was rife throughout the Indian and China seas, all European East India company ships were armed, and very well armed with guns served by expert gunners. This was equally true of all sizable country trading ships, and many of the stronger and more important European trading factories were defended by forts garrisoned by small bodies of troops under European command. There was thus available in southern Asia, and especially on the periphery of the Indian subcontinent and the Indonesian archipelago, a reservoir of European power of a depth and extent largely unrealized because it was unobtrusive and widely dispersed, ever present at sea but hardly visible on land.

In India it was not without significance that the European powers which held almost entirely aloof from Indian disputes were the smaller trading nations—Portugal, the Netherlands, and Denmark. Britain and France were unable to do so primarily because of their involvement in wars with each other over European and American issues. The conditions under which Europeans lived and traded in 18th century India also helped to make it impossible for the subjects of the two foremost European powers to forget national rivalries in the pursuit of individual gain.

Anglo-French Conflict.—However much the directors of the British and French East India companies might wish to neutralize their shipping and their Indian factories from the consequences of war in Europe or in North America, they were

defeated by the impossibility of confining the arena of Anglo-French naval conflict to the Atlantic and by the extensive opportunities open to their servants in India for the acquisition not only of wealth but of power. In the early 1740's the materials for empire building were already at hand. Internecine strife was clearly apparent in southeast India and latent elsewhere. Each contestant for Mughul administrative office or local lordship was eager to acquire European military skill and weapons in exchange for cash, credit, or grants of land. A few Europeans were aware of the possibilities of fashioning armies of European-officered Indian mercenary sepoys and Eurasian artillerymen. More Europeans were anxious to supplement profits from country trading within the Indian seas with profits from military and political activity. The arrival in India of the news that France and Britain, since 1741 *de facto* combatants in the War of the Austrian Succession on behalf of their respective allies, had at last officially declared war upon each other (March 1744) was but a spark to this tinder. Thenceforth, European initiative, enterprise, and greed, armed with powerful European weapons and assisted by Indian disunity and treachery, completed the destruction of the Mughul Empire and laid the foundations of British ascendancy.

The first theater of Anglo-French conflict in India lay in the southeast. Here, in a bewildering series of intrigues, the men on the spot supported their respective candidates for the subahship of the Deccan and the nawabship of the Carnatic. In the first phase the honors were distinctly with the French, not only because of Comte Bertrand François Mahé de La Bourdonnais' capture of Madras (1746), which the diplomats restored to Britain in 1748 at the Treaty of Aix-la-Chapelle, but because of the skill of Marquis Joseph François Dupleix (governor general, 1742–1754) in buttressing his Indian allies' position and initiating in the Deccan the system of a French-officered subsidiary force paid with the revenues of lands especially assigned for the purpose. However, with young Robert Clive's renowned exploit in storming and holding Arcot (Aug. 31–Nov. 15, 1751) to relieve the pressure on the British-sponsored candidate for the nawabship in Trichinopoly (now Tiruchirappalli), the tide began to turn against the French. Dupleix' dismissal (1754) by a government stung by serious military reverses, and under pressure from directors who had never approved Dupleix' policy, may be said to presage French failure in India. Nevertheless, to contemporaries the French in India appeared for many years afterward to have the advantage of the British in military skill and in the arts of Indian diplomacy.

Far more significant for the future were the events which took place in Bengal upon the death of its nawab, Ali Vardi Khan, in April 1756. His young and dissolute successor, Siraj-ud-Daula, perhaps prompted by a desire to prevent the Europeans from behaving in Bengal as they had in the south, rashly drove the British out of Calcutta and thus brought down upon himself the full force of a retaliatory expedition from Madras led by Clive. Bengal then lay exposed both to the exercise of European military skill marshaled by a "heaven-born general" and to the practice of the arts of fomenting treachery by an experienced coterie of Europeans and Indians. The recapture of Calcutta (1757), supplemented by a few months of in-

trigue, sufficed to undermine Siraj-ud-Daula's authority. Plassey, fought on June 23, 1757, was not so much a battle as the essential military climax of a carefully prepared coup d'état which ensured that future nawabs of Bengal would be mere puppets of the British. Despite its bizarre qualities as an engagement in which 2,000 sepoys and 1,000 Europeans defeated a vast Indian army honeycombed with treachery, Plassey may quite appropriately be regarded as the symbol and portent of European domination of India. The ease with which it laid open to conquest and spoliation one of the great Mughul viceroyalties invested it with glamour during the period of British rule. It came to epitomize the curiously complex web of European and Indian interests from which a new order in India was fashioned in the ensuing half century. In 1763, by the Treaty of Paris, French interests in India were reduced to Pondichéry (Pondicherry), Chandernagor (Chandernagore), and a few other small posts.

Development of British Rule.—By 1770 the outlines of the system on which British power was to rest in India began to be clearly discerned. In taking control, with the nominal consent of the almost powerless Mughul emperor at Delhi, of the revenue of Bengal, through the emperor's so-called grant of the *dewanee* (Hindi *diwānī*) in 1765, the British East India Company stood forth as a country power in its own right. Its advantages over other country powers in any contest for supremacy were three: its corporate immortality, its control of naval power, and its possession in Bombay and Madras of subsidiary bases of operation. Its disadvantages lay in its alien character and in the reluctance of its directors to sanction a policy of conquest and expansion.

For an understanding of the manner in which some hundreds of its servants were able in a few decades to secure its recognition as the most powerful of Indian princes, it is necessary to bear in mind the almost constant interaction of European and Indian events. In the London of the 1770's, the return of many a nabob with a fortune, and the prospect of avoiding the export of silver by purchasing homeward cargoes with the surplus revenue of Bengal, convinced both the government and the company that the Indian possessions were of immense and increasing benefit to the British nation. Henceforth, the company's affairs were subjected to ever-closer scrutiny and regulation by Parliament. No one doubted the chaotic and precarious state of the company's finances, but it was felt that, once the company's servants had been prevented from cheating their employer, Indian wealth would flow to Britain in an ever-broadening stream. In India the newly arrived writers, factors, and military cadets were learning of the multifarious ways in which they could become wealthy as a consequence of the company's expanding political activities. Military campaigns, whether connected with the Anglo-French wars in Europe or not, gave opportunity for collusive supply contracts of many kinds. Assumption of governmental functions of any sort usually meant that a company's servant was in a position to bestow favors—for example, exemption from customs duties—for which the Indian mercantile community was willing to pay. Profits from such transactions could be reinvested directly or indirectly in ventures of various kinds, not the least of which were ever-expanding British country trading voyages in the Far Eastern seas.

It is against this background that the wars and annexations of the years 1765–1815 should be viewed. An era of frank spoliation under Clive gave way to a period of more subtle penetration under Warren Hastings (1772–1785). Of Hastings it may be said that his difficulties arose primarily from too great familiarity with Indian institutions and ways of life. To him the company was an Indian power strengthening its influence vis-à-vis other Indian powers. By his opponents, India was seldom thought of apart from its place in British politics. Hastings infused with vigor an administrative machine still largely dependent on Indian personnel. He developed a subsidiary alliance system. Although he did not crush the power of the Muslim sultans of Mysore, Hyder (Haidar) Ali and Tipu Sahib, in the First and Second Mysore Wars, he made the company's sword respected from Delhi to Cape Comorin. Fortunately for Hastings, the American War of Independence ended before France could follow up the naval victories which Admiral Pierre André de Suffren had won for it in the Indian seas. By the time Hastings left India, the bases of British economic and political dominance were firmly laid, and all was ready for the march of British power.

A dramatic personal vendetta between Warren Hastings and Philip Francis had during the 1770's brought India more and more into the public eye in Britain. As a consequence of renewed financial embarrassments growing largely out of the American War of Independence, the affairs of the East India Company were drawn into the vortex of British politics in the early 1780's. The prospects of drastic reforms envisaged by Charles James Fox and his friends alarmed the most powerful among the India interests. After the direct intervention of King George III had caused the defeat of Fox's India bill in the House of Lords, the India interests helped greatly to consolidate William Pitt the Younger in power in 1784. Pitt's India Act, which set the pattern of Indian government from 1784 to 1858, subjected the company's political activities to control by the state but left the company's patronage and commercial activities comparatively undisturbed. After the removal in 1786 of a clause requiring an investigation into the private fortunes of company servants upon their return to England, nearly every European intimately concerned with India was satisfied. British and foreign investors in the company were sure of their dividends. Europeans who had supplied the company in India with funds acquired in devious ways were certain that their bills of exchange on London would be paid. British and foreign agents concerned with remittances from India through non-British channels were sure that if the whole edifice of British power in India did not crumble, no law of the British Parliament could completely destroy their profits. Fixed salaries, supervision by governors no longer closely identified with the company's service, and other reforms were inevitable, but India could still offer attractive opportunities to enterprising Europeans.

To effect a policy of reform and meet the growing public criticism which was soon to culminate in Edmund Burke's orations against Hastings, the Pitt ministry chose as governor general the 2d Earl (later 1st Marquess) Cornwallis, who was to redeem in India a reputation tarnished by the American disaster. Cornwallis,

during the years 1786–1793, more than justified the government's choice. Personally incorruptible, he developed in Bengal an administrative policy which resulted in the efficient professional bureaucracy of the Victorian era. From his day dates the policy of Europeanizing all but the lesser ranks of the civil service which was to prevail throughout the next century. From his day, too, dates the beginning of the transformation of the company's Madras, Bombay, and Bengal armies into something more than mere mercenary forces without any tradition or *esprit de corps*. It was, however, 30 years before the pay and conditions of service in India were such that disaffection among the company's European military officers was not to be feared, and even longer before military efficiency ceased to be impaired by ill feeling between the company's army and the king's regiments stationed in India.

Lord Cornwallis' most lasting achievement, and the one which in the Indian mind has overshadowed all his efforts at reform, was the celebrated permanent revenue settlement in Bengal (1793). This arrangement, with which his name is always associated, though others in both India and Britain bore much of the responsibility for it, had the effect of making the Bengal zamindars (Hindi *zamindār*) not only landlords of the soil in the European sense, but landlords obligated to pay the government a fixed rent which could not be altered under the vastly changed circumstances of the next century. Through the operation of forced sales of the lands of those zamindars whose revenue payments fell into arrears, a new class of zamindars arose largely devoid of the traditional paternal interest in the welfare of their tenants and eager to profit over the years from the increased value of lands on which the revenue charge remained fixed.

Though a faithful adherent of the policy of no aggrandizement enjoined by both company and government, Cornwallis was drawn, largely through the complex machinations of European merchants and company servants, into a full-scale conflict with Tipu, sultan of Mysore (Third Mysore War, 1789–1792). In this contest, Cornwallis had the support of the two other strong country powers—the Marathas and the nizams of Hyderabad. Even after this war, which deprived Tipu of an immense treasure and half of his territory, there was some prospect that the company might be able to forego further territorial expansion. Many of the men most influential in directing policy sincerely wished the company to remain *primus inter pares*, holding the balance among the important country powers and acting, whenever necessary, in the name of a subservient and completely cowed Mughul emperor. The French Revolution, however, extinguished such hopes. Napoleon's Egyptian expedition of 1798 thrust India into the arena of world politics. In the person of the 1st Marquess Wellesley, governor general from 1798 to 1805, there came out to India a great proconsul who turned the company's ally, Nizam Ali, into a feudatory (1798); destroyed Tipu (Fourth Mysore War, 1799); took the first and most decisive steps in the conquest of the great Maratha chieftains; and paid no attention to the company's concern over its ever-mounting Indian rupee debt.

Meanwhile, British mercantile interests outside London, newly strengthened by the then imperfectly perceived consequences of the Indus-

trial Revolution, were preparing for the final attack on the company's monopoly of the India trade. Although the true economic benefits to the British nation from the increasingly complex process of empire building in India at this period were in all probability of quite modest proportions, few contemporary Europeans doubted that they were enormous. Few of the merchants who so ably marshaled their influence in Parliament to open the trade with India to all British subjects in 1813 realized that the trade thus opened would soon differ profoundly from the India trade carried round the Cape of Good Hope since the days of Vasco da Gama. Nor did they realize that the new trade in which export of machine-made textiles and other consumer goods was to be the dominant element would provide a far firmer base for empire than the old. Thus, as the company was ceasing to be a merchant in India and was concentrating its energies on the administration of its growing raj (Hindi *rāj*), the machine had already begun the work of reducing India's old handicraft industries to a shadow of their former selves. India, for centuries a workshop for Europe, was about to fall completely under the domination of the new workshop of the world. Nowhere was the peace of 1815 more of a *Pax Britannica* than in the lands bordering the Indian Ocean.

BRITISH RAJ (1815–1885)

Political and Military Developments.—In considering the process by which the great bureaucratic Victorian Indian Empire was built, it is perhaps well to summarize the political and military history apart from other aspects of the story. After 1815 there was no turning back. As governor general succeeded governor general, the British color crept over the map—extinction of Maratha power under the 1st marquess of Hastings (1813–1822) by 1818; conquest of Assam, Arakan, and Tenasserim (First Burmese War, 1824–1826), under Earl Amherst of Arakan (1823–1828); annexation of Coorg and strict control over many renowned and ancient Rajput houses under Lord William Cavendish Bentinck (1828–1835). With British power unchallenged from the Bay of Bengal to the eastern edge of the Indus Basin, it was only natural that the prospect of Russian expansion to the confines of India should begin to agitate more and more British minds.

In 1838 there were inaugurated profitless and unhappy policies which, in aiming to secure Afghanistan from Russian penetration, brought in their train defeats, military and diplomatic, which helped prepare the way for the Indian Mutiny of 1857. In brief, without sufficient attention to the slender potentialities of Russian policy or power in this region, without constant and unrelenting adaptation to the ever-changing military situation among Pathan tribesmen and along the Perso-Afghan frontier, an attempt was made in the First Afghan War (1838–1842) to thrust British power beyond the Indus in support of Shah Shuja (r. 1803–1810; d. 1842), an unpopular Afghan chieftain. The war was, moreover, undertaken before the Sikh power in the Punjab was itself subdued (1845–1849), such was the measure of British confidence in the invincibility of the Anglo-Indian military machine under the administration of George Eden, earl of Auckland (1836–1842). There ensued the utter military defeat of 1842, when a faithful pony

brought into Jalalabad the exhausted Dr. William Brydon as the sole survivor of an army of more than 4,000 troops and 12,000 camp followers which had sought safety by retreating through the passes from Kabul.

Although the conquest of Sind (1842–1843) and that of the Punjab (1845–1849) were in a sense byproducts of Afghan disaster, neither these operations nor the marching of armies back and forth in southern Afghanistan could obliterate the consequences of the ill-starred First Afghan War. The spell of British invincibility was broken. Afghanistan was evacuated. The raj had lost face at a time when the Indian masses were becoming dimly conscious of the impact of such new forces as the nonofficial European merchant and plantation owner, the Christian missionary, the steamship, the telegraph, and the railway. Moreover, James Ramsay, 1st marquess of Dalhousie (1848–1856), a young and masterful administrator, pressed on in the 1850's with a policy of annexing the territories of Indian princes who were either without heirs or peculiarly impervious to admonitions of reform from the company's government. This policy culminated in 1856 in the annexation of Oudh, perhaps the worst governed of the premier states, but the one from whose domains most of the sepoys in the Bengal Army were recruited.

Upon Lord Dalhousie's successor, Earl Canning (1856–1862), the storm burst on May 10, 1857. Vexed as the problems of the origins of the Indian Mutiny are, there is no question but that the decisive factor was the widespread belief that the cartridges issued with the new Enfield rifles were greased with animal fats abhorrent to both Muslims and Hindus. Careful study of the first weeks of the mutiny shows no widespread conspiracy, concerted planning, or well-thought-out objectives. This does not mean, however, that various native princes and influential landlords did not join the movement for political motives or that it did not evoke vague stirrings of national consciousness among some of those chiefly concerned. Later investigations have shown that those who assumed positions of leadership organized an administration for the territories they briefly controlled with considerable efficiency and skill. Nevertheless, what took place was primarily a military revolt of one of the company's three armies. The Bombay and Madras armies were unaffected, as was most of the subcontinent outside the regions near Delhi in which the fighting took place.

The mutiny was suppressed with great severity in 1857–1858. The heroic, moving tales of the blowing up of the Delhi magazine, of the siege of Cawnpore (now Kanpur), and of the relief of Lucknow, on which Rudyard Kipling's generation was reared, form only the more colorful side of the story. The mutiny left a legacy of bitterness which persisted for at least a generation, but, even more important, wherever it may not have fostered hatred, it fostered the type of aloofness in the ruling race which the increasing number of Western-educated Indians most resented. In government the mutiny caused the dissolution of the East India Company and brought British efforts to modernize and reform the great Indian princely states to an abrupt and unnatural halt. The Government of India Act of 1858 transferred all the East India Company's authority to the crown, and provided for the administration of India through a secretary of

state for India in the British cabinet.

With British dominance throughout the subcontinent assured after the suppression of the mutiny, the officials concerned with India's foreign policy became more preoccupied with the problem of the northwest frontier. Here the persuasiveness of the forward school and the belligerent imperialism of Benjamin Disraeli combined to produce a Second Afghan War (1878–1880) almost as inglorious as the first. The 1st earl of Lytton (viceroy, 1876–1880), unable to readjust his Afghan policy quickly to Disraeli's diplomatic triumph over Russia at the Congress of Berlin, became involved in a war which did little to pacify the frontier, greatly increased the Indian debt, and left on the Afghan throne in Abdur Rahman Khan (r. 1880–1901) a chief who had every reason to prefer Russian to English influence.

Social and Economic Developments.—In Lord Lytton's day the men who staffed the great bureaucracy which had been built up during the two previous generations were of a somewhat different stamp from those who had served Lord Hastings. In 1815 the company's patronage system was still vigorous, and a young man's hopes of an Indian career depended on his connections. In the next 60 years there occurred a gradual extension of the Indian services beyond the coterie of families connected with East India interests in the 18th century. Among such families varying social backgrounds had been represented—chiefly London merchant and shipping families, lesser country gentry, and younger sons of Scottish nonnoble houses—but by the early 19th century all were characterized by close association with India and Indians. Furloughs in those days were infrequent, keeping a European wife and children in India was a hazardous venture, and it was difficult to cut oneself off from Indian life. By 1880 all this was profoundly changed. The introduction of competitive examinations for the Indian services in 1853 tended to confine them to the best brains of the English university world, a world which can hardly be described as other than socially select. Improvements in communications and sanitation made it possible for nearly all British officials to keep British wives and children in India. Inevitably the European station with its club grew up beside the military cantonment, its life divorced from the surrounding Indian world.

Improvement in communications led to the perfection of the bureaucracy. The most remote post office came into immediate contact with headquarters. A subordinate army of Indian clerks and messengers was available to copy and move the mountains of official papers which made the wheels of government revolve. At the top stood the viceroy, struggling desperately not to be buried under the ponderous files, and unquestionably the most hard-worked official in her majesty's dominions. Disraeli's action in 1876 in making Queen Victoria empress of India was criticized as out of keeping with British tradition, but it effectively symbolized the transformation which had taken place in Indian government since the days when the East India Company had a personality of its own.

In 1833 began the social and educational changes which were to lead to the first meeting of an Indian National Congress in 1885. This was the time when the effects of the Reform Bill of 1832 and the reform and free trade move-

ments in Britain began to be felt in India. The company lost its monopoly of the China trade and became merely a vehicle for governing India, dominated largely by men who had served in India. The home government, however, was controlled by Whig politicians immersed in the Reform Bill struggle who had little experience of India. It was hardly extraordinary that they should stand for an ever-wider extension of Christian missionary enterprise and the introduction of an educational policy favoring the teaching of English and the dissemination of European rather than Oriental learning. Missionary policy had long been settled on the understanding that the government would continue its policy of neutrality with respect to all religions. Active controversy in the early 1830's concerned educational policy.¹ The older generation of company servants, who knew something of the values of Indian learning both ancient and modern, were no match for the brilliant Thomas Babington Macaulay, future historian of the English Revolution of 1688. Macaulay, who came out to make his fortune as the new law member of the governor general's council in 1834, wrote in February 1835 the famous minute which was decisive in determining the English character of higher education in India.

With respect to elementary education, decisive action was not taken until 1854, when the dispatch of Sir Charles Wood (later 1st Viscount Halifax) declared that both English and vernacular languages should be used in diffusing European knowledge. The officials who drafted this dispatch, realizing the impossibility of securing enough persons qualified to teach English in the elementary schools, were inaugurating a policy of extensive government support to vernacular education for the masses. There had thus evolved by the postmutiny period the educational policy which was to become typical of modern India: stress on European learning, instruction in the vernacular at the elementary level, higher education on a British model, government grants-in-aid to all properly managed schools willing to accept government inspection, and equal treatment of each school accepting the conditions, irrespective of communal or other affiliations.

At the apex of this educational system stood the three universities of Calcutta, Bombay, and Madras, founded in 1857, which turned out year by year an ever-increasing stream of young men to swell the numbers of the small English-knowing, Westernized middle class. Under the circumstances of the time most of these graduates aspired to become lawyers or government servants. Though chiefly influenced by their reading of English history and literature, they were far from immune to the currents of change which were sweeping in upon their own cultural heritage, whether Hindu or Muslim. Already for a generation orthodox Hinduism had been under attack from reformers who wished to purge it of those practices and customs most objectionable to Europeans. It was therefore quite natural that these new ideas should appeal to large numbers among the newly educated middle class, and equally natural that, in contrast, a small group among these new graduates should react in exactly the opposite manner. Such young men, having read not only their own literature but the works of European scholars on the ancient Hindu past, were moved to protect their heritage against what

they regarded as undesirable innovations. There thus appeared among those Hindus from whom the supporters of nationalist movements were to come two schools of thought—the one certain that India's only wise course lay in the full and unquestioning adoption of the ideas and political institutions of its rulers, the other rejecting most of what the West had to offer and seeking India's new golden age in its ancient past.

Among Muslims the effects of the new university education were markedly different. Far fewer of them took advantage of its opportunities—a circumstance greatly regretted by their descendants when the days of freedom for India were fast approaching. Not only did the mutiny throw their whole community under a cloud for several years, but their cultural leadership lay primarily with religious leaders fanatically devoted to the traditional Islamic Arabic and Persian learning. When a lay leader did appear in the person of Sir Sayyid Ahmad Khan in the 1870's and 1880's, he felt that the only wise political course for Muslims was complete loyalty to British rule and wholehearted and unquestioning acceptance of Western political ideas, to be taught in a university of their own—Aligarh Muslim University, which he founded in 1875 as an "Anglo-Arabic" college.

By 1885 civil and military government servants, businessmen, missionaries, and schoolmasters had built in India an empire very different from that over which the East India Company had presided. In 1815 the company's domain was still a country power, pre-eminent among country powers, and ruled by men whose outlook was often as much Indian as British. Most of these men believed in a policy of noninterference with Indian life and society and in limiting India's contacts with Europe to those arising from the commercial and administrative activities which ensured their own well-being. In 1885, India had become the greatest modern colony, a vast domain ruled by a *corps d'élite* sent out for that purpose by an alien European power.

INDIAN NATIONAL DEVELOPMENT (1885–1947)

Although one or more Indian nationalist bodies met annually from 1885, the general history of India and the histories of Indian nationalist movements were not closely intertwined until after World War I. The Victorian bureaucratic machine moved ponderously on, hardly paying any heed to nationalist agitation except when moved to action by some overt act. Liberal-minded viceroys like George Frederick Robinson, 1st marquess of Ripon (1880–1884), were the exception, not the rule. The raj occupied itself with the perfection of antifamine programs, with army unification (1893), and with irrigation projects. British rule was assumed to be permanent. The storm raised by Lord Ripon's attempt to deprive Europeans of their privilege of being tried always before European judges (Ilbert bill; 1883) enjoined a continued policy of caution as far as indianization of the civil services was concerned. Nevertheless, indianization was begun on a modest scale, and was accepted as an inevitable goal of future policy. Before 1906, however, there was no serious consideration of extending self-government beyond very modest dimensions.

In the 1st Baron (later Marquess) Curzon of Kedleston (1899–1905), India received a proconsul of Wellesleyan stature exactly a century after

Wellesley. Though not a century behind the times, Curzon was peculiarly blind to Indian sensibilities. His partition of Bengal into two provinces, made in the interests of bureaucratic efficiency, exasperated the rapidly increasing number of politically conscious Indians both within and outside Bengal. This action was perhaps the most important single factor which ushered in the period when peaceful nationalist agitation was occasionally embarrassed by the commission of political crimes of various sorts. It was greatly to the credit of the philosophic Liberal, John Morley (later Viscount Morley of Blackburn), who became secretary of state for India in 1905, that he did not allow himself to be diverted by sporadic acts of violence from his plans for drastic Indian political reform.

Morley-Minto Reforms.—Lord Curzon's departure, hastened by his dispute with Viscount (later 1st Earl) Kitchener of Khartoum over the latter's proper functions as commander in chief in India (1902–1909), prepared the way for the first major step toward Indian self-government. The Morley-Minto reforms (Indian Councils Act) of 1909 introduced the elective principle for some seats in the governor general's Legislative Council and greatly increased the elective element in the provincial legislative councils. All this, however, was done on a basis of representing various communities, chambers of commerce, and other similar groups. In accordance with this principle, Muslims, who had sent a special deputation, led by Aga Khan III, to the viceroy, Gilbert John Elliot-Murray-Kynynmound, 4th earl of Minto (1905–1910), in 1906, received separate representation. This granting of separate electorates to minorities, though later vehemently criticized by Indian nationalists, was quite in keeping with the most advanced and liberal British thought of the day with respect to broadening the base of Indian government. Nearly every Briton who studied the subject intimately at that time held that the British parliamentary system was entirely unsuited to Indian conditions. Not only was anything like universal suffrage for India regarded as unthinkable, but everyone assumed that the problem was to give the intellectuals and the propertied and influential segments of Indian communities a feeling that they had a share in the government of their country.

Consequently, by 1910 the autocratic nature of Indian government was hardly changed at all. The Morley-Minto reforms, however, did have the effect of causing many of the intellectual moderates prominent in nationalist bodies to feel that they had not labored in vain. Psychologically, the appointment of one distinguished Indian to the governor general's Executive Council, coupled with the association of many others in the high administrative and legislative spheres, marked a sharp break with the Victorian past. For this the Indian National Congress was largely responsible. It had met annually since 1885, when Allan Octavian Hume, a retired civil servant, and a few of his friends assembled about 100 people in Bombay with the benevolent acquiescence of the government. Year by year the organization had grown. Europeans, Parsis, and Muslims were prominent in it from its earliest years, but inevitably the majority of its members were Hindus, among whom lawyers from Calcutta and Bombay predominated. Its continued existence and the success it achieved in bringing pressure to bear upon the government caused

Muslim religious leaders and landlords to realize how far the Muslim community had lagged behind the Hindu in producing an English-educated minority eligible for high government posts. The Muslim League was therefore formed in 1906.

The success of the great imperial durbar (Hindi *darbār*) of 1911, when the capital was moved to Delhi and the partition of Bengal was reversed, on the occasion of the coronation of King George V, was in itself a testimony to the strength of the British raj. All that nascent nationalism had accomplished was to associate with durbar government a handful of distinguished Indians, most of whom were out of sympathy with the National Congress. In Gopal Krishna Gokhale and Bal Gangadhar Tilak, Indian nationalism had produced its first great figures, the one a moderate, the other an extremist who was thought of as the inspiration of the increasing number of political assassinations. In 1913, however, the raj seemed more stable than ever and would doubtless have been capable of resisting change for many years had it not been for World War I.

World War I and Postwar Reforms.—World War I profoundly disturbed the placid currents of Indian political and administrative life. Not only did Indian troops fight in France and the Middle East, but the best of the British civil and military administrators were drawn away from India. Nationalists had a practical demonstration of the ability of Indian government to function without the accustomed quota of British personnel. When it appeared toward the end of the war that British officialdom was intent on returning to the old order of things, great resentment and frustration spread over India. Racial bitterness reached a climax with the Amritsar massacre of 1919, when Brig. Gen. Reginald Dyer ordered troops to fire on an unarmed mass meeting in an enclosure with only one very narrow exit. Nearly all politically conscious Indians felt that India's great efforts in the war had been betrayed, and that the Montagu-Chelmsford reforms (named for Edwin S. Montagu, secretary of state for India, and Frederic Thesiger, 3d Baron Chelmsford, viceroy from 1916 to 1921), then being framed into the Government of India Act (1919), were very inadequate as an implementation of the solemn British wartime promise (Aug. 20, 1917) of "... the gradual development of self-governing institutions with a view to the progressive realization of responsible government in India as an integral part of the British Empire. . . ."

Nevertheless, the Montagu-Chelmsford reforms of 1919 definitely broke with the idea that India must follow some other path than that leading toward parliamentary self-government. The reasons for this change are complex, but it was a natural consequence of the attainment of a separate international position by the British self-governing Dominions during the war and at the peace conference. India, despite its juridically dependent status, could hardly be denied many of the privileges accorded to the Dominions, notably the privilege of signing the peace treaty separately and of becoming in its own right a separate member of the League of Nations. It was also accorded much more independence in fiscal policy than had been customary before the war. Moreover, the phrase "responsible government" used in the declaration of 1917 was, in view of its history in the Dominions, generally interpreted as meaning responsible cabinet government of the

British parliamentary type.

The Montagu-Chelmsford reforms set the pattern which was to determine the actual administration of India from 1919 until the eve of independence. The central government at New Delhi underwent almost no change between 1919 and 1946; the system by which the British crown's paramountcy over Indian princely states was exercised changed slightly in form but not in substance. In the provinces there was change: full autonomy on April 1, 1937 (when the Government of India Act of 1935 went into effect) replaced the partial autonomy granted in 1919, but World War II supervened so quickly that full provincial autonomy was to a large extent stillborn. In brief, what the Montagu-Chelmsford reforms did at the center was to set up a bicameral legislature—the upper house (Council of State) chosen by an electorate of approximately 80,000 and the lower (Legislative Assembly) by an electorate of approximately 1 million (registration, about 5 million). Nominated members were still an important element in both houses; in choosing elected members communal electorates were used extensively. Legally, the executive remained authoritarian and bureaucratic, not responsible to the legislature and buttressed by extensive emergency powers. Practically, the central legislature was a fairly effective forum for the ventilation of grievances, accomplished much useful work, and, paradoxically, despite its powerlessness attracted some of the ablest Indian politicians, especially at times when nationalists were not boycotting the government and refusing to take their seats. In the provinces the reforms introduced dyarchy—that is, the turning over of certain departments, such as those dealing with education and other “safe” subjects, to Indian ministers responsible to majorities in the lower houses of the provincial legislatures. Naturally, the system did not work well. The Government of India Act of 1935 granted full provincial autonomy and expanded the provincial electorates to cover approximately 33 million voters, but provincial governors retained ample emergency powers, including that of assuming full powers of administration in the event of political deadlock.

Political and Economic Developments of the Interwar Period.—Within a decade after the end of World War I serious Hindu-Muslim differences in the nationalist movement began to appear. Among the causes for the disappearance of the earlier atmosphere of harmony, dating back to 1916 when the Congress had reluctantly acquiesced in the existence of Muslim electorates, must be listed the new revolutionary fervor imparted to the Congress movement by Mohandas K. Gandhi; the fiasco of the caliphate agitation (protest by Indian Muslims against the Treaty of Sèvres) of 1920–1922; Mohammed Ali Jinnah's emergence to leadership among the Muslims in contrast to Gandhi as leader in the Congress; and increasing fear among Muslims of Hindu domination of any centralized parliamentary government. In his philosophical nonviolence, Gandhi developed a technique difficult for Muslims to understand, and he further baffled Muslim nationalists by calling off a civil disobedience movement, because of outbreaks of violence (at Chauri Chaura), in 1922 when it seemed to be succeeding. At the time of the caliphate agitation, Mustafa Kemal (later Kemal Atatürk), by setting up a nonreligious Turkish state, and the Moplas (Malayalam *Mappila*, Muslim peasants of Malabar),

by killing Hindus in southern India, greatly embarrassed the Muslims and Hindus who were attempting to mitigate the terms of the Treaty of Sèvres. As Gandhi developed the peculiar religious quality of his hold over the Indian masses, it was natural that Muslims, especially those of the more conservative and less revolutionary types, should turn to Jinnah or to other Muslim leaders.

The immediate occasion, however, of serious Hindu-Muslim rift was the Nehru report of the Indian National Congress of 1928, resulting from the challenge of British conservatives that Indians had many criticisms of the existing government but were never willing to draw up a blueprint for a new one. Under the chairmanship of Pandit Motilal Nehru, a distinguished committee drew up a constitution for India on a dominion-status basis. Since it was not a federal constitution and made no concessions to Muslim susceptibilities, Muslim opinion was alienated. An All-India Muslim Conference gathered at Delhi under the aegis of the Aga Khan. Representatives of the Muslim League, now solidly behind Jinnah, and of nearly all other Muslim organizations, proclaimed in 1929 the Muslim 14 points, which insisted on separate Muslim electorates, a federal government with residual powers in the provinces, a three-fourths majority rule in legislatures on all communal questions, and appropriate Muslim representation in both provincial and federal cabinets.

During the decade 1929–1939 the Muslim-Hindu rift steadily widened. Each of the great parties—the Congress and the Muslim League—perfected its organization under its own high command and gradually reduced to insignificance the smaller nationalist organizations, whether moderate, such as the liberals led by distinguished Indians who tried to find a compromise in a non-revolutionary program, or extremists, such as the Hindu Mahasabha, which desired a Hindu raj. Henceforth the communal question was in the forefront of all Indo-British political discussion.

British officialdom, realizing the futility of a further approach through an all-British parliamentary commission, assembled the leading Indian princes and political leaders in London in 1930–1932 for three round-table conferences after publication of the report of the Simon Commission (named for Sir John Simon, later Viscount Simon). Gandhi, who had in the spring of 1930 dramatized the Congress struggle by a no-rent campaign and by a march to the sea against the government salt monopoly, was persuaded to make an appearance at the second conference. Nothing, however, could break the communal deadlock. Prime Minister Ramsay MacDonald found himself compelled, much against his will, to authorize a British communal award, allocating seats to the different Indian communities in the legislatures of the proposed new federal Indian constitution.

Six years of discussion (1929–1935) at last produced in the Government of India Act of 1935 a new Indian constitution. Nothing, however, could get the federation, so laboriously worked out on paper, into being. The princes, at first willing to accede to the federation, shied off in such numbers that the federal part of the act remained a dead letter. The Congress Party, which had always inveighed against the scheme as being too heavily weighted in the princes' favor, was not loath to see it die. The Muslim League, with its

fears of a Hindu raj, was also not displeased with the result. Thenceforth, the political struggle shifted to the provinces, where, under the act, full autonomy was to be tested for the first time. Following much searching of heart, the Congress Party decided upon a policy of accepting office in the provinces after receiving assurance that the governors' special powers would not be frequently or unreasonably used.

Soon after the act of 1935 went into effect (April 1, 1937), Congress ministries took office in 7 of the 11 provinces of British India, all of them Hindu-majority provinces except the North-West Frontier Province, where Khan Abdul Gaffar Khan, the Frontier Gandhi, and other Congress Muslims had built up a strong following. (Later a Congress ministry also took office in Assam.) During the ensuing two prewar years, the Muslim League accused the Congress of establishing Hindu tyrannies in the six Hindu-majority provinces (Madras, Bombay, United Provinces, Bihar, Orissa, Central Provinces) which denied Muslims their legitimate rights, especially in educational and cultural matters, and precluded the possibility of their ever wielding any political influence in these provinces. On its side, the Congress Party insisted that it did endeavor to give Muslim interests their due weight and that the Muslim League distorted every Muslim grievance for propaganda purposes.

The ministers of these new provincial governments were the leading personalities in a Westernized middle class of landlords, merchants, and lawyers far more prosperous, numerous, and sure of themselves than had been their predecessors of the previous generation. The two decades since 1918 had been characterized by great economic progress. Large-scale irrigation projects, especially in the Punjab, had been successfully pushed forward. Famine control had been developed to the point where major disasters were regarded as entirely preventable. The Indian Medical Service had much increased its efficiency in combating plague and other tropical diseases. Centers of agricultural research like the government-operated one at Pusa in Bihar and the famous American missionary one founded by Sam Higginbottom at Allahabad had improved cattle breeds and milk production.

Although the industrial labor force was only a tiny minority among a vast peasant population living close to the margin of subsistence, the development of large-scale industry in textiles and steel brought wealth to families such as the Birlas at Calcutta and the Tatas at Jamshedpur. Much of this wealth was at the disposal of nationalist leaders, thus giving the nationalist movement an economic strength which it had not possessed in the 1920's. Indian fiscal autonomy, conceded after the Treaty of Versailles, had given India considerable power to protect its own industry, and its cheap labor costs had stimulated to some extent its exports to other parts of Asia. Preoccupation of most middle-class and propertied Indians with the struggle against their foreign rulers muted possible antagonism among themselves on class and economic issues, leaving Hindu-Muslim antagonism the one great threat to national unity.

World War II.—World War II thus found the two great Indian communities more deeply divided than ever. The Congress Party proclaimed itself a noncommunal organization striving to achieve India's freedom through nonviolent revo-

lution. The Muslim League frankly professed its communalism and sought support as the protector of 94 million Indian Muslims (1941 census) against the prospect of Hindu domination. Such was the situation when the Congress Party leaders ordered all the Congress ministries out of office in October 1939 on the ground that they could not participate in an imperialist war thrust upon India without its consent. This course naturally had the effect of placing the Muslim League in a stronger position than the Congress during the war. When much of Indian political life was necessarily suspended, whether or not wartime emergency measures were in force, Jinnah and other Muslim leaders were out of jail and free to develop for propaganda purposes the plan for a separate Muslim state called Pakistan, first suggested in 1933 by some Muslim students at Cambridge University. In 1940 the League adopted its famous resolution that "the areas in which the Muslims are numerically in a majority, as in the northwestern and eastern zones of India, should be grouped to constitute independent states in which the constituent units shall be autonomous and sovereign."

In March 1942, at a very dark period of the war, Prime Minister Winston Churchill's coalition government sent Sir Stafford Cripps to India with an offer which has since been the occasion of much controversy. Its main purpose was to gain the cooperation of both the Congress and the League with the existing government by transferring to Indians on a *de facto* basis all power save that of the command of military operations and by emphasizing dominion status with consequent option of secession from the British Commonwealth as the immediate postwar British program. Negotiations broke down mainly as a consequence of the difficulties inherent in the plan for ensuring effective British control of military operations. In the postwar part of the offer, however, the prospect of partition was hinted at in the provisions whereby dissatisfied provinces could stay out of the proposed union and form a union of their own on a dominion-status basis. The Congress Party therefore publicly condemned the offer for too great indulgence toward the Pakistan idea, while the Muslim League condemned it for precisely the contrary reason.

In the Quit-India campaign which followed the rejection of the Cripps offer, Gandhi, Jawaharlal Nehru (who had long been recognized as the nationalist figure next in importance to Gandhi), and all the other Congress leaders were arrested along with several thousands of their followers in August 1942. Each side accused the other of precipitate action; the viceroy, Victor Alexander John Hope, 2d marquess of Linlithgow (1936–1943), insisted that widespread violence was planned, while Gandhi insisted that his arrest precipitated the violence. While Indian troops and resources made their contribution to victory and bureaucratic government prevailed not only in New Delhi but in most of the provinces, all political progress was at a standstill. Despite Gandhi's release on medical grounds in May 1944, the deadlock continued until, with the assurance of victory in Europe, more and more of the Congress leaders were freed in the first half of 1945. Gandhi's conversations with Jinnah in September 1944 had frustrated the hopes of those who believed that the two men could agree on some formula that would reconcile their differ-

ences on the Pakistan issue.

Independence and Partition.—While Viscount (later 1st Earl) Wavell, viceroy from 1943 to 1947, was releasing political prisoners, planning to broaden the Executive Council, and preparing for the new elections scheduled for the winter of 1945–1946, the whole scene was changed by the overwhelming victory of the Labour Party in Britain in July 1945. The election tended to remove the Indian nationalists' reluctance to believe that Britain was really determined on a full transfer of power untinged by imperialism. Within 10 months a conference attended by all political leaders was held at Simla in an unsuccessful effort to set up an interim national government (June 1945); new elections were held (November–December 1945); and a British cabinet mission came out to India to form a plan of breaking the Congress-Muslim League impasse (March 1946).

The cabinet mission's plan, announced in a white paper on May 16, 1946, endeavored to keep India united while permitting Muslim-majority provinces to group themselves together with a great deal of autonomy. It set up a feasible procedure for the election of a Constituent Assembly by the 1,585 newly chosen (January–April 1946) members of the provincial legislatures, with 93 seats to be awarded to nominees of the princely states. Moreover, it gave assurance for the first time of Britain's readiness to abandon paramountcy over all the princely states. Neither Congress nor the Muslim League felt it wise to refrain from ultimate acceptance of the plan, but before the summer was out both parties were engaged in a dispute as to various points of interpretation. In September, Lord Wavell brought matters to a head by allowing a newly appointed Executive Council to function as an interim government led by Jawaharlal Nehru. This speedily caused the Muslim League leaders to review their decision and brought about an agreement to enter the government despite non-recognition of the League's contention that it was the only body representing Indian Muslims. For a fleeting moment foreign observers thought a Hindu-Muslim accord would be reached, but it soon appeared that the government seldom if ever functioned normally. Ministers of the opposing groups seldom met face to face, and most cabinet business was done by correspondence. Moreover, the Muslim League let it be known that League members elected to the Constituent Assembly would not take their seats.

This situation remained virtually unaltered in December 1946 after Lord Wavell had succeeded in inducing Nehru and Jinnah to fly to London for conferences on the clarification of the cabinet mission's plan. When such clarification had accomplished nothing in making the interim government workable, the British government decided (February 1947) to replace Lord Wavell with Viscount (later 1st Earl) Mountbatten of Burma and to announce that Britain would withdraw from India by June 1948 in any event, transferring power preferably to one government, but not hesitating to transfer it to more than one government if such action proved unavoidable. This fateful announcement caused intense political activity behind the scenes at both London and New Delhi. On June 3, 1947, came the announcement of the plan for the partition of India into two independent dominions—India and Pakistan. The Indian princely states, no longer under Brit-

ish suzerainty, would be left free to accede to either dominion or not, as they chose. Both the Congress and the Muslim League accepted the plan.

An Indian Independence Act was passed through the British Parliament with very little debate in July, and on the appointed day, Aug. 15, 1947, the British Indian Empire ceased to exist. In its stead, after great communal disturbances in the Punjab and Bengal, which took a toll of many thousands of casualties and involved the migration of several million persons, there appeared two new nations, the one, India, covering most of peninsular India, since nearly all the princely states fell within its orbit; the other, Pakistan, with its 70 million population (1947), the most populous Muslim state in the world, composed of two disparate blocs of territory—in the northwest, Baluchistan, Sind, the North-West Frontier Province, and western Punjab up to a line drawn just east of Lahore; in the northeast, the Muslim-majority districts in eastern Bengal and the Sylhet District of Assam. Despite the continued membership of both countries in the Commonwealth of Nations, all politically conscious Indians hailed the end of the era of European rule which had so imperceptibly begun two centuries before.

19. HISTORY SINCE 1947

Political Integration.—In August 1947, when power and paramountcy were formally relinquished by the British, the territory which is now the Republic of India was composed of a motley of 9 governor's provinces, 5 commissioner's provinces, and more than 500 princely states, and operated under a political structure conceived more than a decade earlier whose federal provisions had never been tried. One of the most remarkable achievements in postindependence Indian history was the reduction of this geographic chaos into a relatively simple administrative structure and the emergence of a strong central government to fill the gap left by the departure of the British raj.

By 1949 all the major princely states within India's purview except Hyderabad and Kashmir had been integrated with the Indian Union by means of cajolery, threats, and the provision of ample pensions for the princes. Hyderabad, a Hindu-majority state ruled by a predominantly Muslim aristocracy, attempted to establish its sovereignty as an independent country. Civil unrest within the state, including the harassment of Hindus seemingly with official encouragement, brought the dispatch of Indian troops in September 1948, in what was officially called a police action. In November 1949, the nizam of Hyderabad acceded to India, and in 1956 his domains were divided among Andhra Pradesh, Mysore, and Bombay.

The State of Jammu and Kashmir, on the other hand, was ruled by a Hindu maharaja and aristocracy, while the majority of the population was Muslim. Like Hyderabad, it postponed the question of accession. In October 1947, when it

looked as if Maharaja Hari Singh were leaning toward India, tribesmen from Pakistan's North-West Frontier Province, with Pakistani cognizance, invaded Kashmir in an attempt to capture the state government. Indian troops were quickly flown in, and open warfare broke out in the central valley west of the capital, Srinagar. Meanwhile, on October 27, the maharaja acceded to India. On Jan. 1, 1948, India brought the matter before the United Nations Security Council, hoping to label Pakistan as an aggressor under Article 35 of the United Nations Charter. The council, on April 21, passed a resolution establishing a United Nations Commission on India and Pakistan (UNCIP) that was supposed to arrange for a plebiscite. UNCIP did succeed in arranging a cease-fire on Jan. 1, 1949, and on the following July 30 the two countries ratified an agreement on a cease-fire line whereby Indian troops would occupy the Vale of Kashmir, Ladakh, and Jammu, while tribal irregulars and Pakistani troops would occupy a sparsely settled mountain district called Azad (Free) Kashmir. An elected Constituent Assembly convened in Kashmir on Oct. 31, 1951. On Nov. 19, 1956, its members approved a new constitution which contained a clause stating that no future body, whatever its character, could reverse the accession of the state to India. At Pakistan's insistence, the Security Council, on Jan. 24, 1957, passed a resolution in which it refused to recognize the permanent accession of the state and called once more for a plebiscite. Whatever the *de jure* status, however, Indian-held Kashmir was administered thereafter as an integral part of India.

The political integration of the rest of India took place in two stages. The first, leading up to the position as of Jan. 26, 1950, when the Indian Constitution was inaugurated, created a graduated federal system composed of states in varying degrees of approximation to the position of the former provinces of British India. There were (1) 9 states which until Aug. 15, 1947, had constituted in whole or in part provinces of British India, with the addition of minor princely states within their borders; (2) 8 states formed from former princely states left intact, such as Mysore and Hyderabad, and from unions of states, such as Rajasthan; (3) 10 lesser states or unions which were largely governed by chief commissioners appointed by the central government, and (4) the Andaman and Nicobar Islands in the Bay of Bengal. Meanwhile, pressure mounted to bring the reluctant government to honor a pledge, made by the Indian National Congress as early as 1922, that the administrative units would be reapportioned along lines of linguistic homogeneity. The first linguistic state, Andhra (now Andhra Pradesh), comprising the Telugu-speaking parts of Madras, was inaugurated on Oct. 1, 1953, and on Nov. 1, 1956, the rest of the states were reapportioned on similar lines. Later, in 1960, Bombay was divided into the new states of Gujarat and Maharashtra. A 16th state, Nagaland, was created in Assam in 1962. Agitation by Sikhs in the Punjab, however, did not result in the creation of a Sikh-majority state. While the French enclaves in India were ceded to India—Chander-nagor (Chandernagore) in 1951, and Karikal, Mahé, Yanaon (Yanam), and Pondichéry (Pondicherry) in 1956 (the cession was completed in 1962), Portugal refused to integrate its territories. Finally, in 1961–1962, India moved unilaterally to incorporate them—first the enclaves of Dadra and

Kulwant Roy

An honor guard of lancers drawn up before Rashtrapati Bhavan (President's House) in New Delhi.

Nagar Aveli (Nagar Haveli), and then, following a military attack, Goa, Damão (Daman), and Diu.

Domestic Problems.—Until the constitution went into effect on Jan. 26, 1950, India was governed under the machinery provided by the Government of India Act of 1935, as amended by the Indian Independence Act of 1947. A Constituent Assembly of 303 members, most of whom were elected by the provincial legislatures, sat as an interim legislature. On April 28, 1949, it was announced that India would remain within the Commonwealth of Nations as a republic, accepting the sovereign only as a symbol of the Commonwealth. Under the constitution of 1950, India emerged as a federal republic with powers divided between the central government and the states. In practice, however, the central government proved to have the more important role.

With the problems of establishing a viable government out of the way, India turned its energies to the pressing problems of economic growth. Three Five-Year plans were launched to initiate rapid economic development. The First Five-Year Plan (1951–1956) was highly successful, but the Second Five-Year Plan (1956–1961) and the Third Five-Year Plan (1961–1966) experienced greater difficulty in reaching their goals. In order to speed the pace of development the government played an increasingly dominant role in all aspects of life and, following a resolution of the Indian National Congress Party at Avadi in 1955, adopted a “socialistic pattern of society” as its objective. In practice, this meant nationalization of transportation, communications, major banks, and life insurance companies; establishment of government-owned industries in the fields of hydroelectric power, fertilizers, drugs, and steel; elaborate regulation of other sectors of the economy; sharply progressive taxation; and commitment to rural cooperatives.

In the central government and in most of the states the Congress Party, the leader of the independence movement, enjoyed continual one-party rule. In the first national elections based on universal adult suffrage, held in 1951–1952, it won 44.5 percent of the popular vote and 362 of the

489 elective seats in the House of the People. Far below it was the second largest group, consisting of the Communists and their allies, which won 27 seats and received 5.5 percent of the vote. In the contests for state legislatures the Congress Party showing was nearly as good—42 percent of the popular vote and 68.6 percent of all seats. The party had clear majorities in all except four states, and there it was the dominant partner in coalition governments. In the following years it retained its preeminent position, though not without challenge.

In the second general election, held on Feb. 24–March 14, 1957, the Congress Party retained control at the national level and in 11 states. In the state assembly elections, in which 2,899 seats were at stake, the Congress Party had 1,888 of the successful candidates, the Praja Socialists 195, the Communists and their allies 189, and the right-wing Jan Sangh 46. Threats to Congress supremacy appeared in the loss of an absolute majority in Orissa, in the success in Bombay of a coalition party favoring the division of the state along linguistic lines, and in the election of a Communist government in Kerala. That government was dismissed by presidential proclamation in 1959, however, and the next year was replaced by an elected non-Communist coalition government. The third general election, which took place on Feb. 16–25, 1962, resulted in a slight reduction in the majority of the Congress Party in the House of the People, where it received 361 of the 494 elective seats. Except in Maharashtra, the number of Congress seats in the state assemblies declined, but the party won an absolute majority in all except Rajasthan and Madhya Pradesh, and in these two states it was able to form ministries with independent support.

Jawaharlal Nehru, first prime minister of India (1947–1964), was the undisputed leader of India and of the Congress Party after the assassination of Mohandas Gandhi in 1948. At the time of Nehru's death in May 1964, Gulzarilal Nanda, senior cabinet minister, took over as prime minister, but this was temporary. Within a week, the Congress Party unanimously chose as prime minister Lal Bahadur Shastri. Shastri had previously served as general secretary of the party, had held various cabinet posts, and was one of Nehru's closest advisers.

Foreign Relations.—In the early days of independence, India's attention was directed in the main toward domestic problems, and when the political horizon reached beyond the country's borders, it included only near neighbors. The problems of partition and of establishing a stable and satisfactory relationship with Pakistan were paramount. The bitter hatreds loosed by the communal struggle and the breakdown of law and order in the Punjab drove perhaps 12 million refugees across the borders, more than half of whom came to India. Partition split in half the Punjab and with it the river sources of the vast canal networks that made the region fertile. This division left behind an international dispute that was embittered each time a hydroelectric project threatened to divert water on one or the other side of the border. The original distribution of governmental assets between the two countries was far from peaceful, and contrasting policies on currency devaluation in 1949 resulted in a temporary trade embargo between them. Stories of harassment of religious minorities within the respective countries led to a continuing stream of migrants across

the borders, and a series of riots in Bengal in 1950 brought India and Pakistan to the verge of war. A treaty signed on April 8 of that year by Nehru and Liaquat Ali Khan eased tensions, but relations with Pakistan were not entirely regularized thereafter, and the continuing quarrel over Kashmir kept them strained. A border agreement was reached in 1959, and bilateral talks were held on the Kashmir problem in 1962–1963. But renewed hostilities broke out between the two nations in 1965 until they agreed to a UN cease-fire in September of that year.

On the broader scene, India's influence in world affairs grew immensely after 1947. Although India was a member of the League of Nations, its foreign affairs had been handled through British embassies and commissioner's offices, and its new power was dramatized by the election of Nehru's sister, Madame Vijaya Lakshmi Pandit, as president of the United Nations General Assembly in 1953. A major goal of India's foreign policy in the postwar period was to hasten the end of colonial rule throughout the world. In pursuit of this goal, it supported independence movements throughout Southeast Asia, encouraged Egypt in the Suez Canal crisis of 1956–1957, and exerted continual pressure in the United Nations Trusteeship Council for the rapid granting of sovereignty to dependent areas.

The country also played a central role in encouraging the growth of strong ties among non-Western nations, and it was a leading sponsor of the Asian-African Conference held at Bandung, Indonesia, in 1955. Of particular importance was its courting of friendship with the Chinese People's Republic, which it was the second nation outside of the Soviet orbit to recognize. India repeatedly represented Communist China's case at the United Nations, and, after an initial startled reaction to the Chinese invasion of Tibet in 1950, signed an eight-year agreement (1954) in which it abandoned most of its traditional interest in Tibet and recognized Chinese sovereignty there. When, in 1959, however, the Communist Chinese crushed a revolt of Tibetans against the increasingly dictatorial Chinese rule, India's relations with China were strained. The fleeing Dalai Lama was given refuge in India, and Nehru expressed his disappointment in Communist Chinese conduct. Relations further deteriorated as Communist China laid claim to Indian territory in the Ladakh region of Kashmir and in the North-East Frontier Agency. Beginning in 1959, there were frequent border clashes as Chinese troops moved into the disputed areas. Fruitless talks were held by the two countries in 1960–1961. Then, in October 1962, the Chinese launched a major offensive along the Indian border. After driving the Indian forces back, they announced a cease-fire and withdrew in some areas. Meanwhile, they continued to threaten India in the hope of obtaining recognition of their territorial claims. At India's request the United States and Commonwealth countries furnished military aid.

In general, India assumed an uncommitted role in the cold war. It made great efforts to create and maintain friendly relations with the Soviet Union and the satellite countries of eastern Europe. At the same time, it kept its traditional strong ties with the Western countries, and on more than one occasion played the role of honest broker in cold war disputes. Many nations joined in assisting India's development programs. Financial and technical aid came mostly from the United

States, the Commonwealth, United Nations agencies, the USSR, and West Germany.

NOTE: The foregoing articles on India were prepared under the joint direction of the editors of THE ENCYCLO-PEDIA AMERICANA and Dr. W. Norman Brown, professor of Sanskrit and chairman, South Asia Regional Studies, University of Pennsylvania.

INDIA RUBBER TREE, the name gen-erally given to *Hevea brasiliensis*, which is in-

digenous to the region of the Amazon River and in the tributary areas of Peru, Bolivia, Ecuador, Colombia, and Venezuela. It is a large tree, of slow growth and long life, requiring low-lying, rich soil and abundant moisture. In Brazil it is found scattered wild through the tropical forest, but in Southeast Asia it is grown on plantations. See also RUBBER.

INDIAN AFFAIRS. Early in the history of the North American colonies it became clear that unrestricted individual dealings with the Indians could result only in confusion and conflict. Individual colonies passed ordinances requiring that the acquisition of Indian land be made by purchase with the concurrence of the governor or of the colonial assembly. This policy was expressed for all the English colonies in a royal proclamation issued Oct. 7, 1763, which declared that "the several nations or tribes of Indians—who live under our protection, should not be molested or disturbed in the possession of such parts of our dominion and territories as, not having been ceded to, or purchased by us, are reserved to them." Trading with the Indians was also early declared a government monopoly. Thus, a pattern of government concern for Indians and government dealings with Indians gradually was woven.

In 1775 the Continental Congress created a committee to deal with the Indians and to assure them of the continued friendship of the new nation to be. The Articles of Confederation conferred on Congress "the sole and exclusive right and power of . . . regulating the trade and managing all affairs with the Indians," and in 1779 the United States Congress adopted a resolution reading in part: "... no land (shall) be sold or ceded by any of the said Indians, either as individuals or as a nation, unless the United States of America, or by the consent of Congress."

On Aug. 7, 1789, responsibility for Indian relations was transferred from a congressional committee to the secretary of war; on March 11, 1824, a Bureau of Indian Affairs was created within the War Department; on June 30, 1834, Congress passed the act which set forth the duties of the Bureau of Indian Affairs and forms the charter for much that is still done by it; and on March 3, 1849, the bureau was transferred to the civilian administration of the newly established Department of the Interior.

Purchase of Indian Lands.—The early policy of government purchase of Indian lands has been adhered to consistently, and it may be fairly said that 2.5 million of the approximately 3 million square miles of the United States have been bought from the Indians. While textbooks place great stress on the Louisiana Purchase and other similar transactions with such countries as Great Britain, France, Spain, Russia, and Mexico, the fact is that all the United States acquired in each of these transactions was the power to govern and to tax. Almost all the ceded territory that was not privately owned by Spanish, French, or Russian settlers was still owned by the Indians, and the property rights of all the inhabitants were safeguarded by the terms of the treaty of cession.

How much the United States paid for this land is a matter of conjecture, for in its land transactions with the Indians many treaties called for payment in land, goods, and services and for tax exemption of their reserved properties. Con-

servatively, these payments might be valued at more than \$1,000,000,000. Moreover, many of the trade goods delivered by the whites, such as knives, firearms, and domestic animals, in their impact on primitive society gave the recipients a valuable technological superiority over other Indian tribes and over their environment which cannot be expressed in terms of money.

Treaties and Legislation.—The conquest and enslavement of new areas by more powerful invaders is part of the historic pattern of human relationships. Indians drove other Indians out of coveted territory when strong enough to do so; on each of the continents the various races and peoples have been continuously in movement, displacing one another as one gained in strength and the other weakened. The discovery, conquest, and settlement of the Americas was simply another chapter in this mass movement of peoples. In North America it differed in one essential aspect from past colonial experiences—early in the relations of the colonies with the Indians, it was established that free purchase and sale was to be the basis of dealings between the natives and the encroaching whites. This decision, however, did not prevent continuing quarrels between Indians and whites on the advancing frontier, a frontier which pushed forward more rapidly than the government was able to extend its authority. Repeatedly government commissions were called in to mediate between whites and Indians, and, while usually finding the whites at fault, the commissions were confronted by an accomplished fact, which remained to be legalized by some compromise not too favorable to the Indians or to the government's reputation for fair dealing.

The earlier theory that the United States government in negotiating with Indians was dealing with independent nations—a theory which led to 371 treaties with Indian tribes—was revoked in 1871 by an act of Congress which declared: "Hereafter no Indian nation or tribe shall be acknowledged or recognized as an independent tribe or power with whom the United States may contract by treaty." Thereafter all Indian legislation was dealt with by both houses of Congress. By 1950 there were on the statute books over 5,000 laws on Indian affairs.

This reservation of responsibility for Indian affairs to the national government has resulted in a proliferation of federal activities on their behalf. Congress legislates on such matters as the control of Indian resources, the determination of Indian tribal membership, the inheritance and distribution of property, jurisdiction over major crimes, and dozens of other municipal matters. Tax exemption of Indian lands, wisely demanded by Indian leaders as part of the purchase price for ceded lands, has made state and local governments reluctant to assume the financial burden of community services. The federal government therefore builds and operates schools and hospitals for Indians, builds and maintains roads and irrigation systems, manages forests and grazing lands, directs an agricultural extension service, and works with individual Indians and their leaders in the establishment of local self-government and in the development of Indian enterprises and reservation programs.

At various times new solutions for the Indian problem have been proposed, and many have been adopted. None have proved to be the immediate panaceas predicted by their supporters. The main reason for this has been that in most instances

the decisions were made for the Indians, not with the Indians, and Indian resistance has served to defeat even the most well-intentioned proposals. It was at first thought that Indians might develop as dependent domestic nations, and the tribes were guaranteed their lands free from the interference of predatory whites and allowed to develop self-government. Since the frontiersmen disregarded the guaranteed rights of the Indians and the government did not enforce them, the project failed. On Feb. 8, 1887, the General Allotment Act was passed by Congress; it was designed to break up the larger reservations into smaller tracts, title to which would be given to individual Indians. It was assumed that individual ownership of property was the secret of American success and would therefore contribute to more rapid civilization and assimilation of the Indians. The restrictions on Indian lands were to continue for 25 years and then terminate. The Indians were then to receive clear title to their individual lands. Many tribes resisted the act, and most of the southwestern reservations were never allotted. In the northern areas where allotment was carried out, more than half of all Indian land was lost by the Indian allottee shortly after the relaxation of restrictions; the inheritance of allotments remaining in Indian ownership has resulted in their continuing subdivision between heirs until the inherited portions are too small for productive use.

During the 1890's general statutes were passed for the leasing of Indian lands to whites in the belief that this would increase their productive use and would stimulate Indians through emulation to better farm and grazing practices. This system also failed, because many Indians who preferred to operate their own lands were coerced into leasing. Deprived of their lands, they settled back to eke out an existence from the lease money.

Indian Reorganization Act of 1934.—The most recent attempt to move toward a solution of the Indian problem was the passage by Congress, on June 18, 1934, of the Indian Reorganization Act (IRA). In brief, this law repealed the allotment act and reimposed restrictions against alienation of Indian lands, to stop their loss; authorized the purchase for, or return to, Indian tribes of alienated lands; provided for sustained-yield operation of Indian forests; authorized the establishment of a revolving loan fund to make loans to individual Indians and Indian chartered corporations; authorized loans to Indians for advanced education; provided means of employing competent Indians in government service regardless of civil service restrictions; and provided the machinery for the organization of Indian tribes for self-government and the management of their own resources. For the first time, Indians were allowed the option of electing to operate under an act or to reject its terms. In 1934-1936, 258 tribal elections were held; 181 tribes, representing 129,750 Indians, voted to accept the act, while 77 tribes, enrolling 86,365 Indians, rejected it. Later amendments extended the operations of the IRA to Oklahoma and Alaska, where the process of tribal choice was not required. Whenever a group or village was ready to organize, it might do so.

The greatest gains under the IRA were: (1) the provision permitting tribes to organize as municipal corporations and to assume self-governing rights similar to those of the average Ameri-

can community and (2) the establishment of a loan fund with which to finance individual or group economic development. From the loan funds available from 1936 to 1948, the United States government loaned \$13,809,000. The delinquency rate in repayments was less than 1 per cent—a better record than had been maintained by federal loan agencies serving non-Indians.

The Indian Service.—The majority of Indians are self-supporting, though at a relatively low economic level. Of the \$48,850,589 appropriated for the operation of the Indian Service in 1949, only \$1,550,941 was expended for direct relief. The remainder was spent for furnishing services authorized by Congress or required by treaty agreements. Of the total, \$14,500,000 was spent on the operation of schools; \$10,250,000, on health services and hospitals; and \$11,500,000, on the construction and maintenance of irrigation projects, roads, schools, hospitals, and agency structures. The administration of these services in Washington and in the field cost about \$4,000,000. In 1949 there were 7,496 full-time civil service employees engaged in Indian work, or about one for every 50 Indians; in the same year there was one federal, state, or local employee for every 24 non-Indians. In addition, the Indian Service, doing its own road work, irrigation, and building construction, had about 3,500 temporary employees. In the case of other government agencies, however, such employees would be working for contractors and would not be counted as government employees. If these temporary workers are added to regular employees, the ratio of employees to Indians was 1 to 30. The per capita cost of government services to Indians in 1949 was \$111.21; the per capita cost of government services (other than military cost and debt retirement) for non-Indians was \$200.

Education.—The school census of 1945 showed a total of 92,296 Indian children of school age. Of these, 31,927 were attending public day schools, 7,813 were in mission boarding schools, and 27,252 were in federal boarding and day schools. During World War II, 5,929 left the reservations with their parents and presumably enrolled in public schools, but there is no accurate record. A total of 19,375 were not in any school; of these, more than 15,000 were on the Navajo Reservation, where adequate school facilities were lacking. Between 1945 and 1950 places were made for about 4,500 Navajos in off-reservation federal boarding schools, and a school building program was undertaken on the reservation.

In 1949, the Indian Service operated 238 schools in the United States and 99 in Alaska. They ranged in size from one-room rural schools to consolidated 12-grade day schools enrolling 450 children. There were 17 nonreservation boarding schools in the United States and 3 in Alaska, and 66 reservation schools which operated boarding departments. Between 1928 and 1948 the number of Indian Service high schools had grown from 2 to 33; since the war the number of high school students has quadrupled. Federal Indian high schools are primarily vocational in program, preparing their graduates to make the best use of their native resources or training them for off-reservation employment. These schools are accredited in their home states, and about 20 per cent of their graduates go on to college or advanced vocational training. The Indian Service has never operated any schools of collegiate grade, but instead has encouraged high

school graduates to attend regular colleges.

Resources.—From 1933 to 1948 the resources activities of the Indian Service more than tripled Indian income from agriculture, stock raising, forestry development, and mineral resources.

Health.—The Indian health service has greatly reduced the incidence of tuberculosis among the Indians, although in areas like the Navajo and Alaska, the death rate was still 10 times that of the white population in 1950. Applying the discovery by Dr. Fred Loe, an Indian Service physician, that sulfanilamide is a specific cure for trachoma, that disease has been eliminated on many reservations and greatly reduced on others. Infant mortality rates were still high in 1950, though the Indian birth rate remained so high that Indians were the most rapidly growing group in the general population.

The Health Branch of the Indian Service operates 64 hospitals in the continental United States and 7 in Alaska. In various clinics and through home visits, over 750,000 treatments are given annually, and more than 50,000 individuals receive hospital care.

As a result of a 10-year study in the United States and Alaska of the use of BCG (*Bacillus of Calmette and Guérin*) vaccination as a tuberculosis preventive, it was found that those who were vaccinated were much less likely to develop tuberculosis, and that among the vaccinated group there were 9 times fewer deaths from the disease. The Indian Service is therefore systematically administering BCG vaccination to children born in Indian Service hospitals and to children in Indian schools. In 1950 the Indian Service was building two tuberculosis hospitals in Alaska, at Sitka and Anchorage, supplying 500 new beds, in addition to approximately 200 beds in older institutions. There are Indian Service tuberculosis hospitals in Albuquerque, N. Mex.; Phoenix, Ariz., and Tacoma, Wash. The Indian Service has built tuberculosis wings for several public hospitals and contracts with their managements for the care of Indian patients. In 1950 additional tuberculosis hospitals were planned for the Navajo area.

Alaska Native Service.—The three native groups of Alaska are under the care of the Alaska Native Service, the title under which the Indian Service operates there. In 1949 the native population of Alaska consisted of about one third of the total, estimated at about 100,000. Indians occupy the interior valleys, and the southeast coastal littoral; Aleuts, the Aleutian Islands, Alaska Peninsula, and the south coast and islands almost to Yakutat; Eskimos, the coastal area, the river deltas, and most of the islands from Bristol Bay north and east to Demarcation Point on the Canadian border. Of the estimated 10,500 children of school age in 1950, 2,950 were attending Alaska territorial schools. About 5,200 were in federal day schools operating in native villages, on in the three boarding schools (of which two are high schools). There were about 600 pupils in mission schools. By 1950, however, no schools had been built in a number of native villages with a total of 1,750 children.

Many Alaskan villages have organized under the IRA, and have borrowed money to buy or build fish canneries, acquire and operate native stores, purchase boats and other fishing gear, and engage in other economic activities. A number of villages have greatly improved their economic status as a result of this development.

Indian Population and Development.—Despite the policy of removal by which the federal government attempted to move as many Indians as possible from the eastern and southern states and to resettle them west of the Mississippi, some Indians are still found in every state of the Union. Those Indians for whom the Bureau of Indian Affairs has a continuing responsibility are those with whom the government has had treaty relations, or for whom it has undertaken some legal responsibility. These live in 24 states (not including New York, where the basic responsibility for the Indians, by colonial treaties, lies with the state). There are more than 15,000 Indians, many of whom are recognized as such by their home states, who have no connection with the Indian Service; most of them live along the Atlantic seaboard and gulf coast. The 1945 census of the Office of Indian Affairs showed 392,000 Indians, compared with a low of 240,000 in 1900 and an estimated 800,000 in 1492.

Oklahoma has the greatest number of Indians, and Arizona is second; California, New Mexico, and South Dakota each have over 20,000. The Navajo is the largest tribe, with more than 65,000. The Sioux are next, followed closely by the Chippewa; both number 35,000 to 40,000.

While many Indian tribes were in 1950 fast moving toward the time when their affairs need no longer be supervised by the government, there were still many tribes which had received little attention in the past and had made little progress toward adapting their ways to modern economic demands. Thousands of individual Indians, however, are constantly taking their places on an equal footing with their white neighbors.

Inter-American Indian Affairs.—The First Inter-American Congress on Indian Affairs was held at Pátzcuaro, Mexico, April 14-24, 1937. Representatives of 19 American nations were present, Canada being the single abstainer among nations with an appreciable Indian population. The United States and Mexico took the leadership in seeking methods for raising the educational, health, and economic standards of the almost 30,000,000 Indians of North, Central, and South America. One of the important results of the congress was the establishment of an Inter-American Indian Institute, with headquarters in Mexico City. The convention authorizing this also provided for the establishment of national Indian institutes in the collaborating nations. Although the United States was quick to approve the convention, Congress, because of World War II, has not appropriated funds for a national Indian institute in the United States. The Second Inter-American Congress on Indian Affairs, held in June 1949, at Cusco, Peru, reviewed and amplified many positions taken at the first meeting.

WILLARD W. BEATTY,
Chief, Branch of Education, Bureau of Indian Affairs.

INDIAN HEAD, Canada, town in Saskatchewan, 50 miles east of Regina. It has extensive grain interests, lumberyards, a home for

aged men and an orphanage. Situated in a wheat-growing region, Indian Head also has grain elevators and flour mills. An agricultural experiment station and forestry school are maintained here by the government. Pop. 1,802.

INDIAN HEAD, the name of several mountains in the United States.

INDIAN HEAD, New Hampshire, a mountain and tourist settlement, near the Old Man of the Mountain, at the southern extremity of Franconia Notch, named for its close resemblance to an Indian profile.

INDIAN HEAD, Bergen County, New Jersey, the highest point (altitude, 550 feet) of the Palisades along the Hudson River; so called because it somewhat resembles the head of an Indian.

INDIAN HEAD, Greene County, New York, in the Catskill Mountains; altitude 3,585 feet.

INDIAN HEMP (*Apocynum cannabinum*), variously called black Indian hemp or Canada hemp, a member of the dogbane family (Apocynaceae), is a perennial herb about one to two feet high with ascending branches, opposite leaves, and small greenish-white tubular or ovoid flowers. It is found in open ground or thickets throughout eastern North America and west to California. The tough bark yields a crude fiber variously used by American Indians for cordage or weaving. The dried rhizomes and roots of Indian hemp and its closely related species, *A. androsaemifolium*, contain a cardioactive principle, apocynamarin, used as a cardiac stimulant or diuretic. See also DOGBANE.

INDIAN LANGUAGES, American. The Western Hemisphere is the region of greatest native linguistic diversity in the world, with mutually unintelligible native languages counted in the hundreds, and many more dialects. Some native languages are spoken by millions of people; others by a dozen individuals or less. Many languages formerly in use are now extinct, and many others are on the verge of extinction. On the other hand, the discovery of hitherto unknown languages continues to take place. Adequate grammars exist for only a very small fraction of the known languages, and for the majority, little or no morphological data are available. In fact, for very many, the available data are limited to a small vocabulary gathered by a traveler or missionary with little or no knowledge of phonetics.

Any relationship between the American Indian languages and any language of the Old World remains unproved. Suggestions of connections with native Australian or with Malayo-Polynesian languages have not been accepted by American linguists. The most likely possibility, yet unproved, is that a very distant relationship exists between the Na-Dene group, composed of the morphology or grammar of all American Athabaskan, Haida, and Tlingit subfamilies, and the original Sino-Tibetan (Sinitic) linguistic stock.

No general statement can be made concerning the morphology or grammar of all American Indian languages. The popular impression that they are primitive, simple, and lacking in grammatical rules is entirely false. Almost all have morphologies which are more complex than those of Indo-European languages, and probably all have some sounds, unfamiliar to Western ears,

which are not found in European tongues. A few of the American Indian languages possess a pitch accent, such as is found in Chinese.

In the United States, speakers of Indian languages are relatively few, and only a small number of Indians, mainly women, are ignorant of English. The largest group of these are members of the Navaho tribe. In Mexico, Guatemala, Ecuador, Peru, Bolivia, and Paraguay there are millions of natives speaking Indian languages, and, generally, no other.

The most important Indian languages of Mexico and Guatemala are Aztec, Otomi, Zapotec, Mixtec, Tarascan, Totonac, Huastec, Mixe, Maya, and Quiche. Those of South America are Carib, Arawak, Tupi-Guarani, Ge, Quechua, Aymara, Chibcha, Mataco, Guaycuru, Araucanian, Tehuelche, Pano, Tucano, Puinave, and Catukina. Aztec, Maya, Quiche, and Quechua have become secondary culture languages in their respective regions, and standard orthographies were developed for them by the Spanish. Tupi has become a lingua franca for much of Brazil, and Guarani is a secondary language in Paraguay.

The many American Indian languages were originally grouped into some 150 separate stocks, or families, presumably independent and entirely unrelated. These numbered 55 in the United States and Canada, and, according to different authorities, 24 to 30 in Mexico and Central America and 57 to 94 in South America. Already this number has been greatly reduced, and further simplification will follow greater knowledge and study.

Mainly on the basis of studies of similarities in structure, John W. Powell's original grouping of 55 Indian language families in the United States and Canada has been reduced to 5. Although proof is still lacking, this classification generally has been accepted by authorities. It includes: (1) Eskimo-Aleut; (2) Algonkian-Mosan, including the Salish languages; (3) Na-Dene, including Athabaskan, Tlingit, and Haida; (4) Macro-Penutian, including Uto-Aztecan, Sahaptian, Kiowan, Tanoan, Zuni, Maya, Totonac, many languages on the Pacific coast, and others in Mexico; and (5) Hokan-Siouan, a very large group, including Siouan, Caddoan, Iroquoian, Muskogian, Yuman, many languages of California, and some in Mexico and Central America. The latter family may even extend to South America. Most of the languages of Mexico and Central America, as far south as the northern border of Costa Rica, belong either to the Hokan-Siouan and Macro-Penutian groups, or to the great Otomanguean family. Tarascan is apart.

The majority of the South American languages are grouped into phyla, families, or stocks of Cariban, Arawakan, Macro-Tupi-Guaranian, Macro-Ge, Macro-Guaicuruan, Chiquitoan, Kechumaran, and Macro-Chibchan. There are, however, a large number of languages not included in any of the above families, and future studies probably will change this classification greatly. See also INDIANS, AMERICAN.

Author of "The Languages of South American Indians."

INDIAN MUSIC. The music of the Central American and South American Indians has been relatively unavailable; hence, little can be said concerning its style and native function. On the other hand, that of the tribes in the United States and Canada is becoming increasingly well known, through the work of scholars and through commercial recordings, numbering several hundred, which are readily obtainable. There is a large and vital unwritten literature of North American Indian music, which ranges from brief, sometimes comical, love songs and social dance songs to complex ritual chants, which may contain 500 or 600 songs with elaborate texts of symbolic sacred poetry. The music is largely vocal, and musical instruments are used chiefly to accompany the singing. These consist of a large variety of drums and rattles, with a scattering of flutes, flageolets, whistles, and rasps. Among a few groups, even a rare one- or two-stringed fiddle is found.

Although the music varies greatly from tribe to tribe, a few generalizations concerning it may be made. There is almost no part singing. Songs tend to be brief (except in rituals), and the meter is often irregular. The vocal style is frequently very tense and richly ornamented with sharp accents, yells, and the use of falsetto and rough or nasal tones. In a great many cases the melody starts high and moves down as the song progresses. Both on ceremonial occasions and in other contexts the singing is done principally by men.

Despite the fact that only tentative definitions of Indian "music areas" have been made, there are certain stylistic features shared in these areas which are worth mentioning. The Indians of the northwest coast and the Eskimos have recitative-like songs with much changing of pitch and complex rhythms. The melodies of the Great Basin Indians have a small range, are characterized by paired phrases, and are sung with a relaxed voice. Those of the California and Yuma Indians rise part way through the song and are also sung in a relaxed voice. The melodies of the Athabaskan group have only two note values, use large intervals, and may employ falsetto. Characteristic of the Plains Indian songs are their melodic "terraces" and complex phrasing, and their rendition in a very tense voice. Pueblo melodies are like the Plains', but are lower in pitch and are sung in disciplined unison. The music of the Eastern Indians is characterized by antiphonal singing and complex scales.

There are indications that Indian music persists even after other aspects of the culture have been lost. Indians living in New York City meet periodically for "song trades," and a lively exchange of songs takes place when members of different tribes encounter each other in "Indian shows." New religious movements produce new music, such as that of the Shaker Church on the

northwest coast or that of the rapidly expanding pantribal Native American Church (Peyote cult). These songs are Indian in structure, but may show the influence of white American culture in their texts and in some aspects of their religious function. A growing number of social dance songs borrow words and phrases from English and include references in their texts to such contemporary objects as automobiles and airplanes. The following stanza from a skip-dance song, translated from the Navaho, shows both these features:

"Girl friend, buy me a car;
We'll go home in style!
Yippie yai yai, yai yai!"

The white influence on Indian music has been slight so far, but the impact of Indian music on white American culture has a long history. Such composers as Frederick Russell Burton, Charles Wakefield Cadman, Arthur Farwell, Frederick Jacobi, Thurlow Lieurance, Edward McDowell, Ethelbert Nevin, and Charles Sanford Skilton have borrowed extensively from Indian models, adapting Indian motifs to the Western European musical idiom. Authentic as well as imitation Indian songs may be found in grade-school songbooks throughout America, and authentic Indian music is studied and learned in the Boy Scout movement and similar organizations having an interest in Indian lore. The serious study of American Indian music is part of the curriculum in a number of American universities where courses in ethnomusicology are offered.

INDIAN MUTINY. See INDIA—18. *History: 1707-1947* (British Raj, 1815-1885); *SEPOY—Sepoy Mutiny*.

INDIAN OCEAN, that body of water which is bounded on the north by India and Iran, on the east by the Malay Peninsula, the islands of the East Indies and Australia, on the west by Arabia and Africa, and on the south by Antarctica. The Cape of Good Hope and the southern extremity of Tasmania are usually considered to be the western and eastern limits of the Indian Ocean.

In the southern part, between Africa and Australia, the ocean is about 6,500 miles wide, narrowing gradually northward. Latitudinally, the Indian Ocean ranges from 70°S. to 30°N. With an area of about 28,350,000 square miles, it is the smallest of the three oceans, comprising less than 21 per cent of the ocean-covered part of the globe. Its gulfs are the Red Sea, the Persian Gulf, the Gulf of Oman, the Arabian Sea, the Bay of Bengal, and the Great Australian Bight. Relatively few large rivers flow into the Indian

Ocean. Among them are the Indus, Ganges, Brahmaputra, Irrawady, and Euphrates. The estimated total land area draining into the ocean is about 5,050,000 square miles. Bathymetric surveys made during the latter part of the 19th and early 20th centuries by the *Challenger*, *Gazelle*, and *Valdivia*, and subsequent expeditions of the *Discovery II*, *Willebrord Snellius*, *Dana II*, and other vessels, added considerably to our knowledge of the relief of the ocean floor. A longitudinal ridge, known as the Great Indian Ridge, extends from India to the Antarctic, separating the Western Indian from the Eastern Indian trough. The former extends from the Bay of Bengal to the Antarctic without significant interruptions. The latter is divided up into a series of basins. In the north the Andaman and Nicobar Islands and the Laccadives-Maldives-Chagos archipelago group each mark the site of a great submarine mountain range.

Between India and Africa is the Carlsberg Ridge, believed to continue northward to Murray Ridge, and to the south to the Mid-Indian and Kerguelen ridges. To the southwest of Carlsberg Ridge lies the Seychelles-Mauritius or Mascarene Bank. Occasional submarine gullies like the Swatch-Of-No-Ground in the Bay of Bengal and the Indus Swatch are believed to be either submerged river beds resting on the continental shelf or caused by the deposition of mud and silt brought down by the rivers. The greatest depth in the Indian Ocean is found in the Sunda Trench, where soundings of 7,455 meters have been obtained.

Madagascar is the largest of the Indian Ocean islands. While Ceylon and Socotra are continental islands, the Laccadives and Maldives are essentially coral islands. The Andaman and Nicobar Islands are peaks of a submerged mountain range. Many oceanic islands like Mauritius, Crozet Islands, and St. Paul's are volcanic in origin.

Overlying the basal rocks of the floor of the Indian Ocean are the muds and ooze that have been gradually deposited ever since the ocean first came into existence.

The monsoonal phenomenon in the region north of 10°S. latitude constitutes the outstanding climatic feature of the Indian Ocean. From about October to April northeast winds prevail in the northern latitudes and northwest winds in the southern latitudes. From about May to September south, southwest, and west winds prevail. South of the latitude of the Seychelles, Chagos, and Cocos islands, the southeast trade winds blow during much of the year. South of 30°S. latitude westerly winds, popularly known as the "roaring forties," prevail. Tropical storms or hurricanes are common in the vicinity of Mauritius. In the Arabian Sea and the Bay of Bengal a few hurricane-type storms occur, mostly during the transitional period between the northeast and southwest monsoons.

The surface circulation of the Indian Ocean has a broad general pattern. The ocean currents in the tropical and subtropical latitudes are directly influenced by the southeast trade winds in the Southern Hemisphere and by the alternating northeast and southwest monsoon winds in the Northern Hemisphere. Near the northern end of Madagascar the westerly Equatorial Current divides into the Somali Current flowing north and the Mozambique Current flowing south between Africa and Madagascar. The latter com-

bines with the South Equatorial Current to form the Agulhas Current. Between latitudes 5° and 10°S. there is a reverse flow of water from west to east, constituting the Contra-Equatorial Current. In the southern sector, the southeast trade drift flows eastward. Farther south surface polar water continually moves northward.

In the deepest levels a mass of water of low density and temperature—the Antarctic bottom drift—moves along the bottom as far north as the Arabian Sea and the Bay of Bengal.

The temperature of the surface water is at all times higher than 20°C. (68°F.) in the tropical and equatorial zones. In the Red Sea and the Persian Gulf the temperature often rises much higher. South of 40°S. latitude the water is generally always cool.

In the Arabian Sea and in a belt from southwest Australia to South Africa, the salinity of the ocean water is high. But in areas under the influence of the monsoons, like the Bay of Bengal, salinity is diminished by heavy rainfall and flow of rivers. South of New Amsterdam and St. Paul's, salinity decreases rapidly.

There is some evidence that the ancient Hindus navigated the Indian Ocean. However, historians generally believe that the Phoenicians first explored the northern part of the Indian Ocean in about the 7th century B.C. Necho II, an Egyptian monarch who flourished about 610 B.C., is reported by Herodotus to have sent some of his vessels, manned by Phoenician sailors, into the Indian Ocean, then known as the Erythraean Sea, to circumnavigate Africa. In the 6th century B.C. the ocean was traversed by Hanno, a Phoenician admiral of Carthage. Arrain, the Greek historian, gives us an account of the coastal voyage of Nearchus, one of Alexander's generals, from the Indus to the estuary of the Euphrates. Hippalus, an Egyptian navigator, who lived about the beginning of the Christian era, was the first to observe the regular monsoons of the Indian Ocean, and to profit by them. In the 9th century the Arabs made frequent voyages across the Indian Ocean. In 1486 the Portuguese rounded the Cape of Good Hope and in 1498 Vasco da Gama reached India by the same route. In 1521 a ship of Ferdinand Magellan's squadron crossed the Indian Ocean in the first circumnavigation of the world.

STANLEY S. GHOSH,
Geographer.

INDIAN PAINTBRUSH, a common name for perennial and annual herbs of the genus *Castilleja* of the figwort family (Scrophulariaceae). They comprise about 200 species, almost all in the New World, and especially in the West. The leaves are alternate and usually dissected. The corollas of most species are greenish or yellowish and inconspicuous, with a long upper lip shielding the four stamens and a very short lower lip. The erect spikes of flowers are made conspicuous by the bright yellow, purple, or red (or in one species, white) tips of the calyx lobes and especially of the bracts that subtend the flowers. Many, at least, are parasitic on the roots of other plants.

INDIAN PIPE, common name of *Monotropa uniflora*, a waxy white or flesh-colored herb in the Wintergreen family (Pyrolaceae) native in dark, rich woods throughout North America and westward into Asia. The rather succulent

stems, with small scalelike leaves, arise in clusters from masses of matted, brittle stems, gaining their nourishment as saprophytes on partially decayed organic matter or as parasites on living roots in the soil. The stems are erect, 4 to 10 inches tall, and bear terminal, solitary, nodding flowers. The flowers are bell-shaped, $\frac{1}{2}$ to 1 inch long, with 4 to 5 white or slightly purplish petals that are hairy within and somewhat longer than the 8 to 10 stamens. The 4- to 5-celled ovary matures to an ovoid capsule. A European species of the same genus, *M. hypopitys*, is yellowish in color and has several flowers instead of one.

INDIAN PLANTAIN, a common name for American members of the genus *Cacalia* in the sunflower family. (Compositae), which comprises some 40 species of alternate-leaved perennial herbs also distributed in northeast Asia. The whitish or cream-colored heads are 5—many flowered, without ray florets, and are borne in flat-topped clusters. The largest American species, *C. reniformis*, reaches 9 feet in height, has dilated, fan-shaped leaves 1 to 2 feet broad. It is distributed from New Jersey to Minnesota and south to North Carolina and Tennessee, flowering in the fall.

INDIAN POKE (WHITE HELLEBORE), common names for *Veratrum viride*, a stout, leafy-stemmed perennial herb in the Lily family (Liliaceae) found in wet places across North America. It reaches a height of seven feet, has broadly oval, pointed, and stem-clasping leaves, and large terminal panicles of small yellowish-green flowers. It is hardy and easily cultivated in moist shady spots for bold effects. The roots of this and other members of the genus are very poisonous, and those of a European species, *V. album*, are powdered and sold as a poison for caterpillars; it is also very toxic to other animals and its use is not recommended.

INDIAN RESERVATIONS. A system inaugurated in 1786 by the United States Congress which set aside sections of land to provide homes for Indians removed from their original lands, for the protection of various Indian groups, or to avoid disputes over land boundaries, but most particularly to facilitate the control of Indians by restricting them to specific areas. A natural outgrowth of land cession, this worked two ways, since many tribes "reserved to themselves" by treaty certain portions of those lands being ceded to the United States. Later wording established reservations by Congressional fiat, in that lands obtained from Indian owners included areas "reserved for the exclusive use and occupancy of" specified tribes.

Reservations were established by the following methods, in order of importance: (1) treaty, (2) executive order, (3) act of Congress, (4) grant from foreign sovereigns, and (5) tribal purchase. Title was acknowledged as based upon the rights of prior occupancy, and as a general rule, the Indian living on the reservation could make no lease nor sale of lands, dispose of standing timber, relinquish mining rights, or rights-of-way without Congressional approval, nor could he leave without agency permission. In return, the government was obliged to establish educational facilities, exercise justice, law and order, prevent the intrusion of outsiders, and prohibit the settlement of others on the reserved lands. Since these obli-

gations were frequently ignored, Indians have traditionally resented being forced to observe their restricted status.

With the passage of the General Allotment Act, also known as the Dawes Act, in 1887, this concept was changed to allow individual ownership of reservation lands; however, the total acreage of Indian-held land was so drastically reduced as a result, the allotting of lands was abolished in 1934.

More recent legislation, particularly as embodied in the Indian Reorganization Act of 1934, has secured for the Indian greater freedom of individual action. Indians are completely free to come and go as they wish; passes are not required of occupants or visitors; and, while some confusion still exists over water rights, Indians may capitalize on the timber, mineral, and other resources of their lands. Much of the reservation land today (1957) is owned by the tribe as a whole, although there is a large amount of acreage held by individual Indians as "allotted" land; these parcels may not be sold without government approval. Reservation lands are exempt from property taxes, although Indians pay income and other taxes.

The several reservations today total approximately 42,785,935 acres, which are administered by the Bureau of Indian Affairs, in the Department of the Interior. This agency has divided the United States into 10 administrative districts, each under the authority of an area director, who exercises considerable control of the Indians within his area. The specific reservations are in charge of agents or superintendents who are subject to the authority of the area director. A few state reservations exist, mainly in the east (such as New York, Massachusetts, and Connecticut). In Alaska the Alaskan Native Service administers reservations for Eskimos and Aleuts. The service comes under the jurisdiction of the Indian bureau. See also INDIAN AFFAIRS and the list of reservations in the United States that accompanies the article INDIANS, AMERICAN.

FREDERICK J. DOCKSTADER.

INDIAN RIVER, a long lagoon in eastern Florida; separated from the Atlantic Ocean by a chain of narrow islands, extending about 150 miles southeast from Volusia County to St. Lucie Inlet in Martin County; and navigable as far north as Titusville to vessels of shallow draft. The river is from 300 feet to three miles wide and is in a famous citrus fruit, and resort section.

INDIAN SUMMER, the name given to a period of mild and pleasant weather which generally occurs toward the end of autumn. The term first made its appearance in the last decade of the 18th century. During the next decade the phrase was "second summer." This indicates that the spell of weather known by this name was not, generally noticed much before 1800. The term Indian summer became established about 20 years after its first appearance, which was in western Pennsylvania, and spread to New England by 1798, to New York by 1799, to Canada by 1821, and to England by 1830. The term is, then, not an Americanism; to write in praise of Indian summer is now a literary convention of three continents.

It is by no means easy to account for the origin of the term. The principal characteristics of the season which it describes are haziness,

smokiness, and high temperature. Some explanations of the origin of the term are that (1) the Indians predicted such spells of weather, (2) the smokiness was produced by Indian fires, (3) this was the last season of Indian attacks on white settlements, and (4) the season partook of the Indian character of deceptiveness.

The spell of cold weather preceding Indian summer was known as squaw winter. Terms analogous to Indian summer used in England are St. Luke's summer, applied to a period of warm weather occurring in October, and St. Martin's summer, referring to a similar period in November.

INDIAN TURNIP. See JACK-IN-THE PULPIT.

INDIANA, ĭn-dĭ-ăn'ă, East North Central state, United States, bounded on the north by Lake Michigan and Michigan; on the east by Ohio; on the south by the north bank of the Ohio River, which divides it from Kentucky; and on the west by Illinois. It extends about 260 miles from north to south and 150 miles from east to west. Its name means "land of the Indians."

From the 1890 census through that of 1940 the center of population of the United States was located in Indiana, which adopted for its motto "The Crossroads of America." In many ways the state is typical of the nation as a whole, with its balance between manufacturing and agriculture, but its people, who are called Hoosiers (the word is of uncertain origin), give it a distinctive flavor celebrated by such Indiana writers as Edward Eggleston, James Whitcomb Riley, and Booth Tarkington.

State flag
(adopted effective May 31, 1917)

State seal
(adopted Dec. 13, 1816)

A discussion of Indiana's geography, government, social and economic life, and history is presented under the following headings:

1. PHYSICAL FEATURES

Topography.—The terrain of Indiana is divided into two types—flat or slightly rolling land in the central and northern sections of the state, and hilly country in the south, with the most rugged hills extending southward from Brown County to the Ohio River. There is little poor soil, but the most fertile is to be found in the central third of the state. The rugged terrain of southern Indiana contains numerous small-scale gorges and canyons. In Crawford County are two large caves, Wyandotte and Marengo, and mineral springs are located at French Lick and West Baden in Orange County. Four fifths of the state, in the center and southwest, is drained by the Wabash and its tributaries, the White, Eel, Mississinewa, and Tippecanoe rivers. The northeastern section is drained by the Maumee, which flows into Lake Erie at Toledo, Ohio; the extreme north by the St. Joseph and the Kankakee; and the south by the Ohio. None of the rivers flowing through Indiana is navigable commercially. There are approximately 1,000 lakes in the northern part of the state. The largest is Wawasee Lake, in Kosciusko County, which covers 3,623 acres. Other large lakes, noted also as vacation resorts, are Maxinkuckee, in Marshall County; Freeman, in Carroll County; James, in Steuben County, on which is located Pokagon State Park; Tippecanoe, in Kosciusko County; and Shafer, in White County.

A basic layer of rock was formed in pre-Cambrian times, but all other Indiana rock strata date from the Paleozoic era. Indiana was under water in the Cambrian, Ordovician, and part of the Silurian periods. In the late Silurian and Devonian periods a ridge known as the Cincinnati arch extended northwestward across the state. Thereafter the land rose, and by the end of the Mississippian period, during which the valuable deposits of Indiana limestone were formed, all of Indiana was above water. In the Pleistocene period five sixths of the area of the state was glaciated, forming deep, rich loams. Only south central Indiana is unglaciated, and here the soil is thinner and less productive.

Climate.—The climate of Indiana is mild, but

Total area	36,291 square miles
Land area	36,205 square miles
Water area	86 square miles
Total area including Indiana's share of Lake Michigan	36,519 square miles
Latitude	37°47'—41°46' N.
Longitude	84°48'—88°4' W.
Altitude (average)	700 feet
High point, Greensfork Township	1,240 feet
Low point, Ohio River	320 feet
Population, 1960	4,662,498
Capital city—Indianapolis; population	476,258
Admitted as the 19th state	Dec. 11, 1816
State bird (adopted in 1933)	Cardinal
State flower (adopted in 1957)	Peony
State tree (adopted in 1931)	Tulip tree
State song (adopted in 1913)	<i>On the Banks of the Wabash, Far Away</i>
State motto (adopted in 1937)	The Crossroads of America
State nickname	Hoosier State

there is considerable variation between the northern and southern extremities. The average temperature for the state ranges from 31° F. in winter to 76° F. in summer. The annual mean temperature is 53° for the entire state (49° for the north and 57° for the south). The growing season in central Indiana lasts 188 days. For the state as a whole the average annual precipitation is 39.2 inches, ranging from 35 inches near Lake Michigan to 45 inches along the Ohio. See also RAINFALL.

Plant Life.—When the first settlers came to Indiana, about seven eighths of its area was forested. The trees, mainly hardwoods, were cut down as the land was cleared for farms, and by 1953 only 4,103,000 acres of forest land, or 17.7 per cent of the total area, remained. Some 725,640 acres of land are included in Hoosier National Forest and in land utilization projects.

Of the 134 species of trees represented in the state, the commonest are the oaks, tulip, beech, sycamore, hickories, maples, and black walnut. Dogwood, elderberries, bittersweet, sumac, and Virginia creeper lend color to the countryside, and violets, lupine, anemones, daisies, asters, and many other varieties of flowers grow in fields, on hill-sides, and along streams.

Conservation.—In 1919 the General Assembly created the state Department of Conservation with the purpose of making "every Hoosier a conservationist, who believes in the state and the laws which are in force to conserve its natural resources for the benefit, education and recreation of all Hoosiers now and to come." Largely under the leadership of the department and its divisions of Geology, Entomology, Forestry, Fish and Game, Engineering, Water Resources, Oil and Gas, and State Parks, Lands and Waters, many conservation programs have been carried out. The conservation of land and water resources has also been promoted by a law permitting county forests to be acquired; by the state Stream Pollution Control Board, which endeavors to prevent or control pollution of streams and sources of water by public or private agencies; and by the Indiana Flood Control and Water Resources Commission. A special program in conservation education was instituted in the public schools in 1945, and many private industries and such civic organizations as garden clubs and chapters of the Isaak Walton League lend their assistance to it.

2. POPULATION AND POLITICAL DIVISIONS

Population Characteristics.—Between 1940 and 1950 the population of Indiana rose from 3,427,796 to 3,934,224 or 14.8 per cent. Although this was a larger percentage rise than had occurred in any previous decade of the 20th century, growth after 1950 was at an even higher rate, and by 1960 the population had increased another 18.5 per cent, to 4,662,498. At the time of the 1960 census, 62.4 per cent of the population was classified as urban.

About 98 per cent of the residents of Indiana are native born. Of these, about 5 per cent are non-white, the majority being Negroes. Of the 100,000 or so foreign-born residents, the major groups are the natives of Germany, Poland, the British Isles, Hungary, Canada, Italy, Czechoslovakia, Yugoslavia, the Scandinavian countries, and Greece.

Political Divisions.—Indiana is subdivided into 92 counties, 544 cities and towns, 1,009 townships, and 313 special districts.

Principal Cities.—Of the 19 Indiana cities with populations (1960) greater than 25,000, six—Indianapolis (pop. 1960, 476,258), Fort Wayne (161,776), Evansville (141,543), South Bend (132,445), Terre Haute (72,500), and Muncie (68,603)—are the principal centers of densely peopled areas classified by the census as standard metropolitan areas. Indianapolis, the capital and largest city in the state, is also one of the largest cities in the United States that is not located on navigable water. An active commercial and industrial center, it has plants processing meat and other foods and manufacturing airplane engines, automobile parts, iron and steel products, drugs, foundry and machine shop products, naval ordnance, optical goods, farm implements, printed material, electrical appliances, paper, hosiery and other clothing, and paints and varnishes. Fort Wayne and South Bend, both in the northern part of the state, produce machinery and a wide variety of other goods. Evansville, on the Ohio River, is the leading industrial center of southern Indiana; it produces refrigerators, automobile parts, meat products, furniture, and machinery. Muncie, in the east, has plants producing fruit jars, electrical goods, furniture, and other goods, while Terre Haute, in the west, is the center of the farming and mining area of the Wabash Valley.

The heavily industrialized cities of the Calumet region of northwestern Indiana—Gary (pop. 1960, 178,320), Hammond (111,698), East Chicago (57,699), and Whiting (8,137)—are included in the Chicago metropolitan area, and Clark and Floyd counties are in the Louisville area. The chief industry in the Calumet is the production of iron and steel.

Counties.—Indiana's 92 counties range in size from Ohio (87 square miles) to Allen (671 squares miles), and in population from Ohio (4,165) to Marion (697,567). A list of counties and county seats follows.

COUNTY	COUNTY SEAT	COUNTY	COUNTY SEAT
Adams	Decatur	Lawrence	Bedford

3. GOVERNMENT

Constitution and Elections.—The constitution of Indiana, the second in the history of the state, was adopted in 1851. It may be amended by a majority vote of each house in two consecutive legislatures, followed by a majority vote of citizens voting on the proposal. The constitution has been amended 20 times. No provision exists for the initiative or a referendum except as authorized by specific statute, and even in such cases the vote is not binding on the succeeding General Assembly.

Ewing Galloway

The state capitol building, Indianapolis.

General elections are held in November of even-numbered years. Party primaries at which all officials except United States senators and elected state officials are nominated take place in May of an election year, while nominees for the United States Senate and elective state offices are chosen at party conventions in May or June after the primaries. A presidential preference primary law enacted in 1953 binds national convention delegates to vote according to the wishes of their constituencies on the first ballot. Thereafter they are free to vote as they please.

Any citizen, 21 years of age or over, resident in the state for six months, in the county or township for 60 days, and in the district for 30 days, may vote in Indiana. Registration is permanent, and absentee voting is permitted.

Indiana sends 2 senators and 11 representatives to Congress.

Executive.—The elective executive and administrative officers are the governor, lieutenant

governor, attorney general, clerk of the state Supreme and Appellate courts, and reporter of the state Supreme and Appellate courts, each of whom is elected for a term of four years; and the secretary of state, auditor, treasurer, and superintendent of public instruction, who serve two-year terms. The governor is limited by the constitution to one four-year term in a period of eight years. No limitation applies to the office of lieutenant governor, but the secretary of state, auditor, and treasurer cannot serve more than four years in any six-year period.

The governor appoints the heads of the departments and is responsible for the preparation of the budget. He may veto any measure enacted by the General Assembly, which may override his veto by a majority vote in both houses.

Legislature.—The Indiana General Assembly, which meets in regular session on the Thursday after the first Monday in January of odd-numbered years, consists of a Senate of 50 members elected for four-year terms, half of them every two years, and a House of Representatives of 100 members elected biennially. The length of regular sessions is limited to a maximum of 61 days. Special sessions called by the governor are limited to 40 days each.

Judiciary.—The highest court in the state is the state Supreme Court, which, together with circuit courts and justice of the peace courts, was created by the constitution. The five justices of the Supreme Court are elected on party tickets for six-year terms. The Appellate Court, which was created by the 1891 General Assembly to assist the Supreme Court, consists of eight judges

elected on party tickets for four-year terms. By legislative enactment the state is divided into 84 judicial circuits, each with a circuit judge who is elected for six years and has jurisdiction over civil and criminal cases; 8 of the circuits comprise two counties each, and the remainder cover one county each. Each circuit elects a prosecuting attorney for a four-year term to handle criminal cases. Additional courts, created by the General Assembly to assist the circuit courts in the more populous counties, include superior courts in 17 counties; probate courts in Marion, St. Joseph, and Vanderburgh counties; criminal and juvenile courts in Marion and Lake counties; and a municipal court in Marion County.

Taxation and Revenue.—A constitutional provision which prevents the state from contracting any debts has helped to establish state finances on a pay-as-you-go basis. Bonds issued by local units of government are limited by constitutional provision to 2 per cent of the assessed valuation of each unit. Approximately four fifths of Indiana's general fund revenues are derived from taxes, of which the principal types are the general sales and gross receipts taxes, a motor fuel tax, alcoholic beverage taxes, motor vehicle licenses, and tobacco taxes, including a per package levy on cigarettes.

Local Government.—The principal units of local government are counties, cities, and towns. County officers provided by the constitution are the clerk of the circuit court, auditor, recorder, treasurer, sheriff, coroner, and surveyor, each of whom is elected for a 4-year term. Except for the surveyor, these officers are limited to 8 years of service in any 12-year period. In addition, there are a Board of County Commissioners, composed of three members elected from districts and entrusted with control of county property; and a seven-member County Council, which approves the county budget, sets the county tax rate, and authorizes county appropriations and bond issues. The county assessor, who is elected for a term of 4 years, supervises the assessment of property for tax purposes.

Cities are divided into five classes by population: first, 250,000 or over; second, 35,000 to 250,000; third, 20,000 to 35,000; fourth, 10,000 to 20,000; and fifth, 2,000 to 10,000. All of them follow the mayor-council form of government. First- and second-class cities have nine councilmen each; third- and fourth-class cities, seven; fifth-class cities, five. The mayor, clerk, councilmen, and, in larger cities, the city judge are elected for 4-year terms. Towns are incorporated places with populations of less than 2,000, or places with larger populations which have elected to continue to operate as towns. Each town elects a board of three to seven members and a town clerk, who serve 4-year terms.

4. EDUCATION, HEALTH, AND WELFARE

Education.—The Ordinance of 1787 creating the Northwest Territory stipulated that since religion, morality, and knowledge are "necessary to good government and the happiness of mankind, schools and the means of education shall forever be encouraged," and the state constitution of 1816 set forth that "it shall be the duty of the General Assembly, as soon as circumstances will permit, to provide, by law, for a general system of education, ascending in a regular gradation, from township schools to a State University, wherein tuition shall be gratis, and equally open to all."

The educational system envisioned under this far-seeing provision was not, however, to be established for many years. The primary efforts of the first settlers were devoted to clearing forests, draining swamps, building log homes, and cutting roads.

Although a permissive educational system was established by the General Assembly, there was no efficient organization, and by the mid-19th century increasing numbers of people began to realize that educational facilities had to be improved. The foundations of the present school system were laid by the constitution of 1851, which provided for a state superintendent of public instruction, and the General School Act of 1852, which established a state Board of Education and set forth an educational program. The successful fight for tax-supported schools "free and open" to all was led by Caleb Mills, Wabash College professor and president.

The duties of the state Department of Public Instruction include administration of the public elementary and secondary schools, school relief and inspection, teacher training and licensing, vocational education and rehabilitation, and school health and attendance. Indiana has had a compulsory attendance law since 1897, and since 1901 attendance between the ages of 7 and 16, inclusive, has been required. Enrollment in the public schools rose from about 500,000 in 1900 to over 1 million in the 1960's.

Indiana has four state-supported institutions of higher learning: Indiana University, Bloomington, with medical schools and a law branch at Indianapolis and with adult education centers scattered throughout the state; Purdue University, Lafayette, and its extension centers; Indiana State College, Terre Haute; and Ball State Teachers College, Muncie. Private colleges include Anderson College and Theological Seminary, Anderson; Butler University and Indiana Central College, both in Indianapolis; DePauw University, Greencastle; Earlham College, Richmond; Evansville College, Evansville; Franklin College of Indiana, Franklin; Goshen College, Goshen; Hanover College, Hanover; Indiana Technical College, Fort Wayne; Manchester College, North Manchester; St. Mary's College (for women) and the University of Notre Dame (for men), both in Notre Dame; St. Joseph's College (for men), Collegeville; Taylor University, Upland; Tri-State College, Angola; Valparaiso University, Valparaiso; and Wabash College (for men) Crawfordsville. College enrollment rose from 5,000 in 1900 to over 100,000 in the 1960's.

Libraries.—Although free public libraries were instituted as part of the public school system established in 1852, most public libraries in the state are independent corporations without direct connection with the public school system. Among the largest of the public library systems in Indiana are the Indianapolis Public Library, which has special collections of children's literature and Indiana authors; the Public Library of Fort Wayne and Allen County; the Gary Public Library; the Indiana State Library, which has a large collection of material on Indiana history; the Evansville Public and Vanderburgh County Public Library; and the South Bend and Hammond public libraries. The largest of the university libraries is that of Indiana University, which has special collections of American literature and American and Indiana history. That of the University of Notre Dame has material on

medieval history, while the Purdue University Libraries are known for their industrial and Indiana collections.

Public Health and Welfare.—The state Board of Health appoints the director of the state Department of Health, which is charged with the administration of public health measures. Under its jurisdiction are the Indiana State Hospital for Chest Diseases at Rockville and Southern Indiana Tuberculosis Hospital at New Albany, and the James Whitcomb Riley Hospital for Children in Indianapolis. A separate Division of Mental Health supervises state hospitals for the mentally ill at Indianapolis (two), Logansport, Richmond, Evansville, Madison, and South Bend; a hospital for the criminally insane at Westville; the Fort Wayne State School in Fort Wayne and the Muscatatuck Colony at Butlerville, for the care and training of the mentally defective; and the New Castle State Hospital, at New Castle. The Indiana Council for Mental Health, created in 1945, has authority to prescribe methods of psychiatric treatment, to set up standards of training for hospital employees, and to organize mental hygiene clinics. Medical and psychiatric care take precedence over custodial care.

The state Department of Public Welfare is responsible for administration of assistance to aged and blind persons, aid to dependent children, and services for crippled children; the supervision of child welfare agencies; and the licensing of nursing homes. The state Department of Correction administers the Indiana State Prison at Michigan City, the Indiana Reformatory at Pendleton, the Indiana State Farm at Greencastle, the Indiana Women's Prison and Indiana Girls' School, both at Indianapolis, and also the Indiana Boys' School at Plainfield. Other state institutions are schools for the deaf and the blind at Indianapolis, a soldiers' home at Lafayette, and a home for the children of soldiers and sailors at Knightstown.

5. ECONOMIC ACTIVITIES

Indiana ranks among the 10 leading states both in value of manufactures and in cash income from farms. The state's per capita personal income, which fluctuates close to the national average, rose from \$553 in 1940 to \$1,520 in 1950 and to \$2,181 in 1960.

Labor.—The state's labor force comprises over 1,600,000 workers. Manufacturing accounts for about 600,000, wholesale and retail trade for 300,000, federal, state, and local government for 200,000, and agriculture for 115,000.

In 1945 Indiana's labor and management leaders adopted the first state labor-management charter, calling for the amicable settlement of labor disputes. In 1954 a successful voluntary mediation and conciliation service was set up by the governor. Indiana adopted a right-to-work law in 1957 to become the first major industrial state to ban the union shop. The state has also enacted legislation barring injunctions in labor disputes. Earlier voluntary fair employment practices were strengthened in 1963 when the legislature passed laws prohibiting discrimination in employment because of race, creed, or color.

Agriculture.—The number of farms in Indiana, as in the United States generally, has declined. The state had 185,000 farms in 1940, 167,000 in 1950, and fewer than 130,000 in the 1960's. The average size of farms, on the other hand, increased from fewer than 120 acres in 1950

to more than 145 acres in the 1960's. The total amount of land in farms has remained relatively constant at just under 20 million acres, valued in the 1960's at about \$275 per acre. This value represented a sizable increase over the 1950 figure (\$136 per acre) and was more than double the national average (\$115 per acre).

About three fifths of Indiana's cash farm income is derived from the sale of livestock and livestock products, of which the most important, in order of value, are hogs, cattle and calves, dairy products, eggs, and broilers. The most valuable cash crop is corn, which ranks second only to hogs as an income producer. The second crop is soybeans, and in the production of both corn and soybeans Indiana normally ranks second or third in the nation. Other leading crops are wheat, tomatoes, oats, tobacco, hay, apples, popcorn, red clover seed, cantaloupes, watermelons, rye, strawberries, peaches, and lespedeza seed. The state is the chief United States producer of spearmint and peppermint, which are raised in the rich muck soil of the northern section. Other important muck crops are potatoes, cabbages, onions, celery, and carrots.

Mining.—Coal is Indiana's leading mineral product. There are approximately 70 mines in the state. Coal is obtained in about 15 counties, but almost nine tenths of total production comes from the 5 counties of Vigo, Warrick, Pike, Greene, and Sullivan. Of the total output, approximately 70 per cent is yielded by strip pits.

Indiana ranks first among the states in the production of building stone, and Indiana limestone is known as the nation's building stone. It is quarried in Monroe, Lawrence, and Owen counties. Indiana limestone was the construction material used for the Rockefeller Center buildings in New York, the Pentagon and numerous other federal buildings in Washington, and many state capitols.

The state also ranks high in the production of ceramics. Most of the clay is found in the west central part of Indiana, and Brazil, seat of Clay County, describes itself as the clay center of the world. Among the products made from Indiana clay are brick and tiles, terra cotta, flowerpots, conduits, jars, and vases.

Another important mineral resource is petroleum. In addition, the state is an important producer of sand, gravel, and cement.

Manufacturing.—The number of manufacturing establishments in Indiana increased from about 4,000 in 1940 to over 6,500 in the 1960's; value added by manufacture rose from less than \$1 billion to over \$6 billion. Almost all the important types of manufacturing are represented. Leading in value are the primary metal industries, of which steel is the most important component. Indiana is exceeded in basic steel production only by Pennsylvania and Ohio, and the Calumet area of Lake County, center of most of the state's basic steel production, is one of the world's largest industrial concentrations. The Gary Steel Works of the United States Steel Corporation is the second largest steel plant in the world.

Other leading industries in Indiana are electrical machinery; food and related products; chemicals and chemical products; nonelectrical machinery; fabricated metals; transportation equipment; stone, clay, and glass products; printing and publishing; rubber and plastic products; and petroleum and coal products.

Power.—About three fifths of the coal mined in Indiana in the 1960's was consumed by electric utility companies, with a capacity of over 6,700,000 kilowatts of electric energy. Other industries had a capacity of about 800,000 kw. Hydroelectric capacity was only 31,000 kw, although undeveloped hydroelectric power was estimated at 700,000 kw.

Banking.—Indiana had a total of about 450 banks in the 1960's, a decrease of about 8 percent from 1950. Bank deposits, however, increased from under \$4 billion in 1950 to over \$5 billion in the 1960's. There are more than 200 savings and loan associations with total assets of approximately \$2 billion.

For additional production statistics, see *THE AMERICANA ANNUAL*.

6. TRANSPORTATION AND COMMUNICATIONS

Indiana's modern highway system covers about 90,000 miles, of which 80,000 miles are surfaced. It includes such heavily traveled federal highways as U.S. 40 (the old National Road) and U.S. 30 (Lincoln Highway), principal coast-to-coast routes, and U.S. 31 (Dixie Highway) and U.S. 41, leading north-south routes, as well as the Indiana Turnpike, completed across the northern part of the state in 1956.

All main railroad lines east of Chicago and many vital north-south arteries pass through Indiana, and Indianapolis is the world's largest inland railroad center not on navigable water. Some 30 railroads, with a combined line mileage of over 6,000 miles, operate in the state.

Indiana, strategically located on the chief north-south and east-west air routes, is served by American, Delta, Eastern, Lake Central, North Central, Ozark, Trans World, and United airlines and a Chicago helicopter line for passengers, and by Slick Airways for freight. The state has more than a hundred commercial airports.

Through Lake Michigan on the north and the Ohio River on the south, Indiana has access to the Great Lakes and the inland waterway system. Gary and Indiana Harbor (the port of East Chicago) are the most important lake ports.

In the 1960's the state had 2 million telephones, over 90 radio stations, 17 VHF and UHF television stations, and 90 daily newspapers.

7. CULTURAL LIFE

In 1890 there was probably hardly a literate person in the United States who had not read Edward Eggleston's *Hoosier Schoolmaster*, some of the incomparable poems of James Whitcomb Riley, or Gen. Lew Wallace's *Ben Hur*. At or soon after the turn of the century many more books had come from the pens of Indiana authors, including *When Knighthood Was in Flower* by Charles Major, *The Song of the Cardinal* by Gene Stratton Porter, *Graustark* by George Barr McCutcheon, *Fables in Slang* by George Ade, and *The Gentleman from Indiana* by Booth Tarkington. Among more recent writers who have continued the Indiana literary tradition are Meredith Nicholson, Theodore Dreiser, Albert J. Beveridge, Ross Lockridge, Jr., Jeannette Covert Nolan, and the World War II GI's columnist, Ernie Pyle.

Interest in state history is fostered by the Indiana Historical Society in Indianapolis, the Allen County-Fort Wayne Historical Society, and the Northern Indiana State Historical Society in South Bend. Indiana University in Bloom-

ington publishes the *Indiana Magazine of History*.

The Art Association of Indianapolis, organized in 1883, maintains the John Herron Art Institute, which is widely known for its teaching of art and has the best museum in the state. Other collections of paintings are displayed in the Fort Wayne Art School and Museum, at Ball State Teachers College in Muncie, and in the O'Shaughnessy Liberal and Fine Arts Hall of the University of Notre Dame. There are a number of local art associations, and in the little town of Nashville in Brown County live many artists, particularly painters. Brown County is a mecca for art lovers and artists, and many well-known studios are clustered in its picturesque hills.

Ewing Galloway

The George Rogers Clark State Memorial at Vincennes.

Indiana has made noteworthy contributions in the field of music. The popular music of Cole Porter, Hoagy Carmichael, and others is internationally known. Connersville is reputed to have been the first city in the United States to have a public high school band, and Richmond claims to have had the first high school symphony orchestra. Perhaps the greatest impact has been made by the Indianapolis Symphony Orchestra (q.v.) and the Indiana University School of Music. Two members of the school's faculty, S. Thomas Beversdorf and Bernhard C. Heiden, are nationally known composers and conductors.

8. PLACES OF INTEREST

Indiana's state park system, one of the finest in the United States, was established in 1916 under the direction of Col. Richard Lieber. It comprises about 35 parks and beaches with a combined area of over 50,000 acres. The parks were developed both for recreation and to conserve typical Indiana scenery and geological formations. They are

scattered from the sand dunes of Lake Michigan to the rugged hills and cliffs along the Ohio River. With their locations they are as follows: Bass Lake, Starke County; Brown County, near Nashville; Clifty Falls, near Madison; Indiana Dunes, near Chesterton; Kankakee River, near Schneider; Lieber State Park, near Cloverdale; Lincoln, containing the site of the cabin occupied by the Lincoln family during their stay in Indiana, near Lincoln City; McCormick's Creek, near Spencer; Mounds, which has the largest Indian earthworks in the state, Anderson; Muscatatuck, near North Vernon; Pokagon, near Angola; Scales Lake, near Boonville; Shades, near Waveland; Shakamak, near Hymera; Spring Mill, which contains a reconstructed pioneer village, near Mitchell; Tippecanoe River, near Winamac; Turkey Run, near Marshall; Versailles, near Versailles; and Whitewater, Union County. There are also state and municipal forests with a total of over 100,000 acres; state fish hatcheries with rearing and display ponds; and about 15 game preserves.

In addition, there are 14 state memorials, which include the first state capitol, at Corydon; the territorial capitol and the George Rogers Clark State Memorial, both at Vincennes; the Tippecanoe Battlefield State Memorial, near Lafayette; and Angel Mounds, the largest group of Indian mounds in the state, near Evansville. Also in Vincennes are William Henry Harrison's home and the Cathedral of St. Francis Xavier, built in 1825-1841. In New Harmony are the buildings of the Rappite colony, and in the city park at Rockport is a reconstructed Lincoln village. The State Capitol in Indianapolis is an imposing structure built of Indiana limestone in 1878-1888. Among other notable buildings in the capital are the Scottish Rite Cathedral, which has a carillon of 63 bells; the Soldiers and Sailors Monument; and the World War Memorial. In Madison, Vevay, South Bend, and Fort Wayne are a number of houses erected in the early 19th century.

9. FAMOUS MEN AND WOMEN

Men and women born in Indiana have attained fame in many fields. In statesmanship they have included three secretaries of state—Walter Q. Gresham (near Lanesville, 1832-1895), John W. Foster (Pike County, 1836-1917), and John M. Hay (Salem, 1838-1905); a vice president, Thomas R. Marshall (North Manchester, 1854-1925); the senators Oliver Perry Morton (Salisbury, Wayne County, 1823-1877) and James E. Watson (Winchester, 1863-1948); Paul V. McNutt (Franklin, 1891-1955), chairman of the War Manpower Commission; and Wendell L. Willkie (Elwood, 1892-1944), most expressive advocate of One World.

Among Indiana's many writers are Lew Wallace (Brookville, 1827-1905), John James Piatt (Milton, 1835-1917), Edward Eggleston (Vevay, 1837-1902), Joaquin Miller (Liberty, 1839-1913), Maurice Thompson (Fairfield, 1844-1901), James Whitcomb Riley (Greenfield, 1849-1916), Charles Major (Indianapolis, 1856-1913), Annie Fellows Johnston (Evansville, 1863-1931), George Ade (Kentland, 1866-1944), George Barr McCutcheon (near Lafayette, 1866-1928), Meredith Nicholson (Crawfordsville, 1866-1947), Gene Stratton Porter (Wabash County, 1868-1924), William Vaughan Moody (Spencer, 1869-1910), Booth Tarkington (Indianapolis, 1869-1946), Theodore Dreiser (Terre Haute, 1871-1945), Charles A. Beard (Knightstown, 1874-1948), Mary R. Beard (Indianapolis, 1876-1958), Lloyd C. Douglas (Columbia City, 1877-1951), Claude G. Bowers (Hamilton County, 1878-1958), George Jean Nathan (Fort Wayne, 1882-1958), Robert S. Lynd (New Albany, 1892-), Ernie Pyle (Dana, 1900-1945), and Ross Lockridge, Jr. (Bloomington, 1914-1948). To the world of art, Indiana has contributed the painters Theodore Clement Steele (Owen County, 1847-1926), William Merritt Chase (Williamsburg, 1849-1916), Otto Stark (Indianapolis, 1859-1926), and Wayman Adams (Muncie, 1883-1959); and the sculptor Janet Scudder (Terre Haute, 1873-1940). Paul Dresser

(Terre Haute, 1858-1906), Cole Porter (Peru, 1893-), and Hoagy Carmichael (Bloomington, 1899-) became celebrated as composers of popular music.

Other famous Hoosiers are James B. Eads (Lawrenceburg, 1820-1887), inventor of the diving bell; Ambrose E. Burnside (Liberty, 1824-1881), Civil War general; the chemists Harvey W. Wiley (Kent, 1844-1930) and Harold C. Urey (Walkerton, 1893-); William T. Hornaday (Plainfield, 1854-1937), zoologist; Eugene Debs (Terre Haute, 1855-1926), labor leader; Elwood Haynes (Portland, 1857-1925), inventor of the first successful clutch-driven automobile; Wilbur Wright (Millville, 1867-1912), pioneer in aviation; Will H. Hays (Sullivan, 1879-1954), president of the Motion Picture Producers and Distributors of America; Eli Lilly (Indianapolis, 1885-), drug manufacturer; Elmer Davis (Aurora, 1890-1958), news analyst; and Lewis B. Hershey (Steuben County, 1893-), director of the Selective Service System.

10. HISTORY

In common with other regions of the Ohio and Mississippi valleys, the territory which now comprises the State of Indiana was once occupied by a prehistoric Indian people popularly called Mound Builders (see MOUND BUILDERS AND MOUNDS). Their earthen forts and embankments, mounds, and village sites dating back to pre-Columbian times are found in about one third of Indiana's 92 counties. The most important of the Indian tribes in historic times was the Miami (see MIAMI INDIANS).

Indiana's recorded history began late in the 17th century, when Robert Cavelier, sieur de La Salle, explored the region. Following one of the two principal routes by which the early French explorers traveled from the Great Lakes to the Mississippi River, La Salle and a party of 28 men camped one night in December 1679 on the south bend of the St. Joseph River, en route from Lake Michigan to the Kankakee and Illinois rivers. La Salle returned to this area in the spring of 1681 and, as part of his plan to build a series of French forts from Lake Ontario to the mouth of the Mississippi for the protection of the Western Indians and the fur trade against the Iroquois tribes, held conferences with the Miami and Illinois Indians under a great tree, later known as the Council Oak, at what is now South Bend. La Salle influenced the Indians to move into Illinois, but early in the 18th century the tribes began to return to Indiana, settling on the Maumee, Wabash, and White rivers. During that century, Shawnee, Miami, Delaware, Potawatomi, Kickapoo, and other Indians roved the trackless wilds of Indiana.

In the first third of the 18th century the French established three forts and trading posts in the area. Fort Miami was erected at what is now Fort Wayne, and Fort Ouiatenon was built about 1720 on the Wabash near the site of Lafayette. The most important and only permanent one of the three posts, however, was that established in 1731 or 1732 at Vincennes by Francois Marie Bissot, sieur de Vincennes, in whose honor it was named.

Relatively few French colonists had settled in Indiana by 1763, when the Treaty of Paris ended the French and Indian War with the cession to Great Britain of all lands east of the Mississippi. British soldiers were sent to garrison Western posts, and the Indian region came under the jurisdiction of Col. Henry Hamilton, lieutenant governor at Detroit.

Forseeing the importance of the Old Northwest to the American cause in the Revolutionary War, George Rogers Clark, with financial backing from Governor Patrick Henry of Virginia,

recruited a small army which in the summer of 1778 captured Kaskaskia and took over Fort Sackville at Vincennes. Hamilton, coming down from Detroit, recaptured Fort Sackville in December 1778. Clark, who had remained at Kaskaskia, headed eastward and, after pushing through the flooded lands along the Wabash, surprised Hamilton at Vincennes and forced his surrender on Feb. 25, 1779.

By the Treaty of Paris, in 1783, Great Britain ceded the territory northwest of the Ohio River to the United States. Virginia relinquished her claims in 1784, and three years later the Congress of the Confederation enacted the Ordinance of 1787 (q.v.) for the Northwest Territory. In addition to providing for the government of the territory and for its eventual admission into the Union by states, the ordinance excluded slavery forever and guaranteed basic personal rights. In 1800 the Northwest Territory was divided into two parts, the territories of Indiana and Ohio, and William Henry Harrison was appointed governor of Indiana Territory. With the creation of Michigan Territory in 1805 and Illinois Territory in 1809, Indiana was reduced to its present limits. (See also NORTHWEST TERRITORY.)

Meanwhile, beginning in the late 1780's and continuing for seven or eight years, hostility between the Indians and the settlers grew in intensity. Under the leadership of the Miami chief Little Turtle the Miami and other tribes united against the white men. After defeating militia, first under Brig. Gen. Josiah Harmar (1790) and then under Maj. Gen. Arthur St. Clair (1790), Little Turtle himself met defeat in 1794 in the Battle of Fallen Timbers (see *FALLEN TIMBERS, BATTLE OF*) at the hands of an army led by Maj. Gen. Anthony Wayne. By the Treaty of Greenville (see *GREENVILLE, TREATY OF*) in the following year the Indians ceded a small strip along the eastern side of Indiana as well as most of Ohio to the whites. While additional pioneers moved to Indiana, there was peace for almost 15 years between the whites and the Indians, and Governor Harrison was successful in obtaining the cession of most of southern Indiana and southern Illinois. Tecumseh, a Shawnee chief, then warned that further cessions would mean war and set about forming a confederation of Indian tribes. On Nov. 7, 1811, Harrison defeated the Indians in the Battle of Tippecanoe (see *TIPPECANOE, BATTLE OF*), 7 miles north of where Lafayette now stands. This last major Indian battle in Indiana was followed in the autumn of 1812 by the last big Indian massacre of whites, which took place at Pigeon Roost in the southern part of the territory. Subsequently the Miami and other tribes sold the rest of their lands in Indiana and moved west of the Mississippi. By 1838, when the last of the Potawatomi left the state, only a few Miami remained.

The close of the War of 1812 and the Indian wars which were a phase of it coincided with the end of Indiana's territorial period. A state constitution was drafted in June 1816 at Corydon, and Indiana was admitted to the Union on December 11 of that year. In 1813 the territorial capital had been moved from Vincennes to Corydon, which remained the state capital until 1825, when the seat of government was removed to the new town of Indianapolis.

As settlers swarmed into Indiana—by 1830 the state had a population of 343,031, and by 1840, 685,866—its development was marked by the

flowering and failure of two attempts at communal colonization which attracted wide attention. The first began in 1815, when George Rapp, patriarchal leader of a group of people known as Rappites, and his followers came from Pennsylvania to establish on the Wabash a model community which they called Harmonie. All property was held in common. In 1825, Rapp sold the community to Robert Owen of Scotland, who renamed it New Harmony (q.v.). Owen and his followers continued the practice of common ownership of property, but dissension broke out. Acknowledging defeat, Owen left for England in May 1827, and the experiment came to an end in 1828. Although the communal experiment failed, New Harmony made important contributions to the movement for equal social and legal rights for women and to progressive education.

River transportation, never very successful, was supplemented by winding roads hewed out of the forests. As farmers sought wider markets for their products, these became inadequate, and in the early 1830's the state, with borrowed funds, began the construction of canals. The most important was the Indiana segment of the Wabash and Erie Canal, which was opened between Lafayette and Toledo in 1843. An internal improvement program embracing more than 1,000 miles of roads and canals was begun in 1836, but met with disaster because of extravagance, poor planning, and the panic of 1837. The heavy debt which burdened the young, struggling state as a result of attempting to underwrite these acute growing pains contributed in part to a provision of the 1851 constitution that prohibits the state from incurring indebtedness. Gradually, however, Indiana became more prosperous. Schools and colleges were built, and wood and brick houses replaced the earlier log cabins. Mines and quarries were active, and factories were constructed. In 1854 the Monon Railroad was completed between New Albany and Michigan City. In politics, Indiana remained Democratic until 1837, when a Whig was elected governor. After a short period of Whig popularity the Democrats resumed control until 1861, when the first Republican governor took office.

Many Indianans had come originally from the South, and some of them sympathized with the Confederacy when the Civil War broke out. The majority, however, loyally supported the Union, and under the energetic leadership of Governor Oliver P. Morton, Indiana supplied 208,367 men to the Union cause from a population (1860) of 1,350,428. Although no decisive battles took place on Indiana soil, there were some raids, the most daring being that of Brig. Gen. John Hunt Morgan, who in 1863 swept through Corydon, Salem, Dupont, and Versailles before being captured in Ohio (see also *MORGAN'S RAIDS INTO INDIANA AND OHIO*). A hostile legislature elected in 1862 refused for two years to pass any appropriation bills, and Governor Morton was forced to borrow money on his own credit to finance military operations. Of Indiana's Civil War soldiers and sailors, 26,672 died in battle or from disease.

After the war new factories were built, and roads and railroads were constructed. Agriculture suffered from low crop prices, however, and many farmers and workingmen supported the Greenback and Populist movements. Conditions improved in the early years of the 20th century with the establishment of automobile factories

at Indianapolis and of iron and steel mills in the Calumet region.

In World War I, Indiana furnished 130,670 men to the armed forces, of whom 3,354 died in service, and the state also supplied large quantities of war materials and food. Agriculture enjoyed a boom during the war, but the farmers suffered severely from the postwar collapse in crop prices. Industry remained prosperous until 1929, however, and many new roads and other facilities were built during this period. Both industry and agriculture were hard hit by the depression, but by the late 1930's recovery was well under way, and in World War II Indiana farms and factories made an impressive contribution to the war effort. Over 400,000 Indiana men and women entered the armed services; more than 10,000 lost their lives. Indiana shared in the nation's prosperity after the war, and many new industries were established in the state. New schools and highways were constructed, and the facilities of the colleges and universities were greatly expanded.

After 1861 political control in Indiana was fairly evenly divided between the two major parties, and by 1962 the state had had an equal number of Republican and Democratic governors. In 1940, Wendell L. Willkie, native-son Republican presidential nominee, carried Indiana in his unsuccessful race against Franklin D. Roosevelt, who had won pluralities in the state in 1932 and 1936. From the World War II era into the early 1960's, Republicans dominated the Indiana General Assembly and elected a majority of their Congressional candidates. Thomas E. Dewey (in 1944 and 1948), Dwight D. Eisenhower (in 1952 and 1956) and Richard M. Nixon (in 1960), all Republicans, won Indiana's 13 electoral votes in their bids for the presidency.

Director, The Indianapolis Foundation.

Revised by P. S. SIKES,

Dean, The Junior Division, Indiana University.

INDIANA, borough, Pennsylvania, seat of Indiana County, situated at an altitude of 1,310 feet, 45 miles east-northeast of Pittsburgh. It has freight service via the Baltimore & Ohio and the Pennsylvania railroads. There are bituminous coal mines nearby. The borough is the seat of a state teachers college founded in 1875, and it has plants producing rubber tires, glass furniture, leather goods, sportswear, clay products, concrete blocks, thermostat controls, macaroni, and beverages. Laid out in 1805, Indiana was incorporated in 1816 and is governed by a borough manager. Pop. 13,005.

INDIANA CENTRAL COLLEGE, a co-educational liberal arts college, opened in 1905, affiliated with the Evangelical United Brethren Church. Bachelor of arts and science (education, business) degrees are granted.

INDIANA UNIVERSITY, a state-supported coeducational institution of higher education located principally at Bloomington, Ind. Opened as a state seminary in 1824, it became a college in 1828 and a university in 1838. It is governed by an eight-member Board of Trustees. On the main campus at Bloomington, which covers 1,395 acres, are located the College of Arts and Sciences, the School of Law, the School of Education, the School of Music, the School of Business, the School of Health, Physical Education, and Recreation, the Graduate School, the Division of Optometry, and the Division of Adult Education and Public Services. There is also a Junior Division, which is concerned with the needs of freshman students. On a 75-acre campus in Indianapolis are the School of Medicine, the School of Dentistry, the School of Law (Evening Division), the Training School for Nurses, the Normal College of the American Gymnastic Union, and divisions of Medical Technology, Graduate Dietetics, and X-Ray Technology. There are adult education centers at East Chicago, Fort Wayne, Gary, Indianapolis, Jeffersonville, Kokomo, Richmond, South Bend, and Vincennes. The university publishes the *Indiana Magazine of History* and a number of scholarly journals. The library contains approximately 1,000,000 volumes, including special collections in American history.

INDIANAPOLIS, in-dī-ān-āp'ō-līs, city, Indiana, capital of the state and seat of Marion County, located on the West Fork of the White River, 184 miles southeast of Chicago. Situated in the center of the state at a focal point of industry, commerce, banking, and trade, the city covers a flat terrain (710 feet above sea level) of 55.2 square miles. The town of Woodruff Place is entirely within city limits but has never been annexed. The temperature of Indianapolis averages 28.8° F. in January and 76.0° F. in July. The business district lies in the heart of the city. Scattered about it are public buildings, the Union Station, and the World War Memorial Plaza, which covers five blocks. In general, the residential section is on the north and east sides; the industrial, on the south and west. In 1950, Indianapolis had 134,654 dwelling units, of which 52.8 per cent were owner occupied.

Industries.—In 1954 the Indianapolis standard metropolitan area had 998 industrial establishments employing 75,953 persons; their combined value added by manufacture was \$594,503,000. Among the largest of the factories are those producing telephone sets, inner tubes, saws, engines, television sets, phonograph records, truck bodies, food products, and gloves. The city's stockyards, opened in 1877, cover 210 acres and are the largest east of Chicago. In 1954 there were 4,632 retail establishments, 1,179 wholesale establishments, and 2,554 service establishments in the city.

Transportation and Communications.—In 1957, Indianapolis was served by 7 railroad systems, 20 bus companies, 142 motor freight lines, and 7 airlines. The city had five radio stations, three television stations, and three major daily newspapers, the *News*, *Star*, and *Times*.

Government.—Indianapolis is governed by a mayor and a common council of nine members, all elected for four years. The mayor appoints the boards and department heads, and the council fixes their respective salaries. Members of the board of education are elected by popular vote.

Education.—The city's institutions of higher learning include Butler University, Indiana Central College, Marian College, Indiana University's schools of medicine, dentistry, and law; and extension schools of Indiana and Purdue universities. The city has both public and parochial high schools and elementary schools, as well as kindergartens and special schools, including state schools for the blind and deaf.

Cultural and Recreational Facilities.—In 1950, the Indianapolis Public Library had about 750,000 volumes and 97,015 registered borrowers; the Indiana State Library had 263,830 volumes, mostly nonfiction, including a collection in Braille and the largest existing collection of material about Indiana. Among the city's other facilities are the John Herron Art Institute (and Museum), the Arthur Jordan College of Music, and a children's museum. The city had 32 parks in 1950 covering 3,234 acres, and also 40 playgrounds. It had six city-owned and nine private golf courses, two midget auto racing tracks; American Association Baseball grounds; an arena for ice hockey matches and track for harness racing; and Butler Field House in which state-wide high school basketball tournaments are held annually. The Indianapolis Motor Speedway is the scene of the world-famous annual 500-mile Memorial Day auto race.

Other Points of Interest.—The city is the headquarters of the American Legion, the International Brotherhood of Teamsters, and 50 other nation-wide organizations. In the heart of the city is the Soldiers and Sailors Monument, completed in 1901 as the second highest monument in the United States (285 feet). In the city are more than 500 places of worship, representing all denominations.

History.—Almost four years after Indiana became a state, commissioners approved (June 7, 1820) a place at the confluence of Fall Creek and White River as the site for the state's capital. By Jan. 8, 1825, when the legislature first met in Indianapolis, the capital and county seat of newly-organized Marion County had 600 inhabitants, a brick courthouse, several taverns, a newspaper, and other evidences of growth, though it was not incorporated as a town until 1836. Meanwhile, in 1830, the National Road (later U.S. 40) was extended through the town. In 1847, Indianapolis was incorporated as a city (population, 8,091), and the Madison Railroad was completed giving it an outlet to the Ohio River. The city now began to develop rapidly as an industrial and marketing center, and a hub of the state's overland transportation system. In 1860, the population was 18,611; by 1870, it had risen to 48,244. Three developments of the 1880's and 1890's made for even more rapid expansion: the discovery near Indianapolis of cheap fuel (natural gas) for industry; an interurban trolley system; and the birth of the automobile industry.

Federal census figures show the steady growth of the population: 105,436 in 1890; 233,650 in 1910; 364,161 in 1930; 427,173 in 1950; and 476,258 in 1960.

RALPH F. ARMSTRONG,
Writer and Editor.

INDIANAPOLIS SYMPHONY ORCHESTRA, founded in 1930 as a cooperative organization. It was conducted by Ferdinand Schaeffer until 1936, when Fabien Sevitzky and Vladimir Bakaleinikoff were engaged as guest conductors. The orchestra was then reorganized on a permanent basis and financial management was put in the hands of the Indiana State Symphony Society. Sevitzky was appointed permanent conductor and has held the position since 1937. Eleven pairs of subscription concerts are given each season in the Murat Theatre as well as popular concerts and children's concerts.

INDIANOLA, city, Mississippi, county seat of Sunflower County; altitude 127.4 feet; on the Columbus and Greenville Railroad; 101 miles north of Jackson. Near the center of the fertile Yazoo-Mississippi delta area, it is an agricultural and trading center. Formerly called Indian Bayou, the name was changed to the present in honor of the Indian maid, Ola, and was incorporated in 1886. It has mayor and council government. Pop. 6,714.

INDIANS, American. Christopher Columbus, sailing for the Indies, found instead the New World of the Western Hemisphere and called the native people Indians. This discovery, in 1492, and the centuries of exploration, conquest and settlement which followed revealed to the Europeans a world new in many ways. By the early 19th century the final contact between Europeans and a native group had taken place. Little by little, during recent years, the story of the American Indians and their ways of life in the past and present has been unfolded. But what would Columbus and his companions have seen if their's had been a bird's-eye view of the whole New World and its inhabitants?

By the 15th century the Indians were living in all parts of North, Central, and South America, from the Arctic Ocean to Tierra del Fuego and from the Atlantic Ocean to the Pacific. At that time the Indians probably numbered over thirteen million. Out of this total, about one million lived north of the Rio Grande, over three million lived in Middle America, and about 9 million lived in South America. To European eyes first seeing them, all American Indians looked much alike physically because of their hair and skin color. Actually, in other respects, there has always been some variation in physical type among the American Indians. In head shape, nose form, and bodily height the Indians would have revealed to the early discoverers their physical diversity.

The American Indian languages would have shown an even greater diversity to the Europeans. North and South America together contained more linguistic families than all the rest of the world. Forty different linguistic stocks were represented in North and Middle America and another 40 in South America. At the time of discovery the number of people speaking these different languages varied enormously. Some languages were spoken by only a few hundred people,

while others were spoken by many people spread over large areas. A 15th century bird's-eye view of the New World would have shown an equally amazing variation in the way in which the Indians lived. In several parts of the New World, the European explorers found well-established, complex civilizations with a developed political, economic, religious, and artistic life. Between these peaks of development they found groups following different and simpler ways of life. They found groups living in settled towns and villages with an economy based on intensive farming, hunting or fishing. They also found people leading a simple nomadic life following wild game and gathering wild food. In some areas they found people living in substantial houses of stone or mudbrick near huge palaces, temples or fortresses. Elsewhere the dwellings were simple brush or skin shelters. The Europeans encountered complex, integrated state organizations with class stratification on the one hand and simple band organization on the other.

Sources of Information on the American Indian.—This glimpse of the diversity of physical type, language and way of life suggests a long and complex history for the American Indian prior to the 15th century. What is known of the time and place of origin of these Indians? What is known of the development of their ways of life and how do we find the answers to any of these questions? These topics have long been a favorite subject for speculation as well as for careful study. Most of the speculations about the origin and development of American Indian life have been based on completely superficial observations. Chance similarities between Egyptian civilization and the Maya Indians of Central America, for example, have lead some people to assume a close connection between these two groups. To make this connection practical some people have revived the legend of the lost continent of Atlantis. This same kind of speculation has lead to similar mistaken conclusions about other groups and other lost continents.

What are the careful and valid sources of information on these questions about the American Indians? Most of this information comes from studies made by anthropologists. They, with much help from historians, geologists, paleontologists, and specialists in other fields, have been piecing together the long story of the American Indians. From different specialists within the field of anthropology come the various parts of this story. The physical anthropologists study the skeletal material of the early Indians and the physical characteristics of the living Indians including blood-group affiliation which seems to have some racial significance. From the physical anthropologist comes our information about the racial affiliation of the American Indians. From the anthropologists who specialize in linguistic studies and who compare Indian languages and reconstruct the earlier types comes the story of the Indian languages. Other important sources of information are the anthropologists who specialize in archaeology and in ethnology. By careful excavation the archaeologist uncovers the remains of the prehistoric Indians. This includes skeletal remains, and such material evidence of pottery, houses, weapons and other equipment as survive. From this the archaeologist carefully reconstructs the early history of the Indians.

The ethnologist, by a study of historical docu-

ments and a comparison of living and recent Indian groups adds to the picture.

To complete their work in reconstructing the story of the American Indian, anthropologists receive the help of the paleontologists and geologists in establishing relative dates and time perspective. With the help of the botanists they have worked out the story of such an important native American plant as corn. And very valuable assistance has come from the work of radiation chemists in determining more specific dates for early prehistoric material. The methods and results of this work may still be subject to some modification, but they are now widely accepted. The findings are referred to as "Carbon 14" dates. New evidence is constantly being added to the study of the American Indian, and new interpretations of old evidence are sometimes necessary. But on the broad outlines and the major developments and time sequences in the story there is general agreement.

Peopling of the New World.—It seems certain that the American Indians did not originate in the New World but gradually migrated from Asia sometime after the end of the Ice Age. There is a variety of evidence to support this conclusion. To begin with, no archaeologist has found any human skeletal remains of an extremely early date or of a physical type significantly different from modern Indian types. Some tools, presumably man-made, have been found closely associated with extinct animal bones. But, unlike the situation in other parts of the world, the extinction of these animals was relatively recent in the New World. This absence of early human material is consistent with another line of evidence. Because there are no living anthropoid apes in the New World, and no fossil remains of extinct apes have been found, it seems most unlikely that early man could have evolved there.

Where, then, did the American Indian come from? In his most stable and most characteristic physical traits, the American Indian is like the Mongoloid stock found in most of Asia. They share blue-black color and straight, coarse quality of hair; generally dark skin color; and shovel-shaped incisor teeth. This does not, of course, equate the American Indian and the modern Chinese. It means, rather, that at some time in the past, a group of Mongoloid stock separated from the main group in Asia. After reaching the New World they probably had little or no contact with the main Mongoloid stock and developed certain characteristics of their own. The one New World group most similar to the Asiatic Mongoloids are the Eskimos. They, along with the tribes living in northeastern Asia, are classified as the Arctic Mongoloid race, a division of the Primary Mongoloid stock. All other New World aborigines are classified in the division of the composite Mongoloid stock called American Indian race.

The non-Mongoloid physical characteristics of the American Indians are the unspecialized ones which some authorities have classified as indicating an ancient "white" admixture to the predominantly Mongoloid base. Such a mixture might have occurred in some Indian groups before they left Asia, or they might represent a parental form like the modern whites or Mongoloids but less specialized than either of them. One important difference existed in the setting of the Asiatic and New World groups. The Asiatic Mongoloids were in touch with other racial

INDIAN RESERVATIONS IN THE UNITED STATES

The statistics making up this list were compiled from a variety of federal and private sources, and were carefully summarized to achieve the most accurate estimate possible, in view of the paucity of data. No truly reliable population count of the American Indian has ever been compiled, but it is believed that this table will prove to be as close to reality as can presently be made. Many of these counts were obtained from agency personnel, in substantiation of Bureau of Indian Affairs figures.

Two points should be made clear to users of this listing: (1) It cannot be used to arrive at a total Indian population, since it does not include off-reservation Indians, and (2) the count regards as "Indian" those people enrolled upon tribal lists, those individuals of one quarter or more Indian blood who are included in Bureau of Indian Affairs counts, and those individuals living on reservations and identifying as Indian.

FREDERICK J. DOCKSTADER,
Museum of the American Indian.

The Indian Reservations listed above are presented with the spellings as they appear on the United States government records; locally-used variants are given in parenthesis. It will be noted that some of these reservations are no longer inhabited; these are retained as open land for tribal use in observance of existing agreements. As a few have been withdrawn, and with the normal pulse of politics and population growth, it is to be expected that population statistics and land acreages will change almost annually. Many of these reservations, most notably in New York, are now under state rather than federal jurisdiction; no indication is made of such administrative variation.

AMERICAN INDIANS

Left: Vincent Myers, Comanche Indian of Apache, Okla., at work on his 160-acre farm. A veteran of World War II, during which he rose to the rank of major and won the Distinguished Flying Cross and the Air Medal, Myers was the winner of the Department of Interior's Conservation Award for 1960.

Right: Indians at San Felipe Pueblo Reservation in New Mexico attend a lecture on soil control, as part of the bureau's technical aid program. The over-all goal is to conserve soil and increase crop production.

Left: Adult education class for Seminoles at the Big Cypress Reservation in Florida. In cooperation with tribal governing bodies, the bureau has established adult education teaching units in over 100 Indian communities.

strains, whereas those coming to the New World entered a free territory. One of the most interesting and puzzling differences between the Asiatic Mongoloids and the American Indians is that of blood group affiliation. The American Indian, in general, is very high in group O affiliation and very low in A, whereas O and A are of nearly equal frequency among the Mongoloids. It is possible that this variation occurred in the course of the original adaptation to the New World environment.

A matter which has received considerable attention in discussions of physical characteristics of American Indians is the apparent gradual change from an early, long-headed type to a later, round-headed type. A factor which makes it difficult to assess this difference is the practice of head deformation which was widespread in the New World, and which precludes the accurate measurement of many skeletal remains and living peoples. The question has been raised whether this change, if real, indicates additional migration into the New World or a local development. It should be noted that this same shift has been characteristic of peoples all over the world. Despite this possible variation in head shape, some regional differences in stature and in some minor physical characteristics, the American Indian shows relatively little physical variability. There is, in fact, less variation in the New World than in any comparable area of the Old World.

There is little doubt about the route which these early migrants took from Asia to North America. The two continents are close only at the Bering Strait, where they are about 60 miles apart. At an earlier time this distance was probably shorter, the crossing even easier. When the strait is frozen, it is possible even now to make the crossing on foot. It seems likely that groups of Asian hunters and fishermen, following the game, moved gradually across this area. Finding the climate and the food supply suitable they moved on, not knowing, of course, that they were entering a "new world." This process was repeated many times and the immigrants moved farther and farther south.

When could such migrations have taken place? They must have occurred at a time when climatic and glacial conditions were favorable. About eleven thousand years ago, at the close of the glacial period, the climate became mild enough to have permitted such migration. Earlier than that, glacial conditions would have been unfavorable. Archaeological excavations give no evidence of any human material of an antiquity greater than about ten thousand years. So, on the basis of all present evidence, the time of the first migration seems to have been between ten and eleven thousand years ago.

A peopling of the New World by any route other than the Bering Strait is highly unlikely for a number of reasons. South America is 2,000 miles from the nearest Pacific island. Chance voyages might have occurred over this route but it is most unlikely that a large group or repeated groups could reach the New World in this way. More important still is the evidence that the Pacific islands themselves were only recently settled, perhaps a few thousand years ago. So, despite all speculations about this route, it must be eliminated for these and other reasons.

Evidence of Earliest Culture.—The people who migrated into the New World were nomadic hunters, fishers, and food gatherers whose way

of life was very simple. They brought with them from Asia a knowledge of the preparation and use of chipped stone tools, of projectiles propelled by spear throwers and perhaps shot from bows, the use of fire, and possibly the domesticated dog. The oldest archaeological evidence of an early culture in North America is named Folsom from the place of its first discovery in northeastern New Mexico. Similar material was found in other parts of the Western Plains; near Clovis, New Mexico; near Fort Collins in Colorado; and near Lipscomb, Texas. The projectile points found at these sites are of two kinds, the one rough and irregular and the other very finely chipped. Some of these projectile points were imbedded in bones of extinct bison, indicating that these are quite old even though so skillfully made. But, as has already been mentioned, association of man-made material with bones of extinct animals does not necessarily mean any great antiquity in the New World. The geological evidence for the age of the Folsom culture places it at the end of, or just after, the last glacial period. The Carbon 14 date for this terminal glacial stage is about 8500 B.C. which corresponds closely to the Carbon 14 date of 8000 B.C. for the Folsom material itself. A second kind of early culture, called Cochise from a site in southern Arizona, dates somewhat later in time than the Folsom material and differs greatly from it. The Folsom people were hunters, and left only scrapers, knives, and their unique projectile points. The Cochise people, on the other hand, left few scrapers and knives and no projectile points. They did leave many grinding tools (mortars, handstones, pestles, flat grinding-stones) indicating a seed-gathering economy. From these early cultures there is an unbroken sequence of sites extending to about twenty-five hundred years ago, almost to the beginning of pottery-making and agriculture.

We have seen that man first reached the New World about eleven thousand years ago. By about ten thousand years ago there was a hunting economy in the Western Plains, and, somewhat later, a gathering economy in the southern Arizona area. The seed-gathering Cochise culture persisted, with minor changes and additions right up to the time a few hundred years before Christ, when pottery-making, agriculture, and permanent houses were added, bringing in an era of great culture enrichment. The parallel period for the hunting people is less well-known but it seems possible that such a site as Ventana Cave in southern Arizona represents this period. The earliest layers in this cave contain material of a Folsomlike culture. On top of this there is material similar to the later stages of the Cochise culture. On top of this is a pottery-bearing layer dating from A.D. 1 to A.D. 1400 and on top of this is historic Indian material.

So far, we have been describing material only from the Southwestern United States. This area is well-known because its dry climate has preserved the early material and its lack of heavy vegetation facilitates archaeological discovery. There have been a few other scattered finds. Gypsum Cave in southern Nevada yielded artifacts indirectly associated with bones of extinct animals. The material is undoubtedly early but any exact dating is impossible. The same is true of cave material from southern Oregon, Big Bend sites in Texas, and caves near Salt Lake City. The Boylston fish-weir site in Boston,

which may be four to five thousand years old, gives evidence of man in what is now the Eastern United States. Folsomlike points are found at the bottom of middens in the Eastern United States, left by hunting and gathering peoples. These middens date from 1000 to 3000 B.C.

At Tepexpan in the Valley of Mexico a human skeleton, elephant bones, and flake tools were found in one stratum. The evidence is not conclusive proof of early habitation of this site but it is promising.

Evidence from several parts of South America indicates that early migrants reached many parts of that continent, even distant Tierra del Fuego. The earliest archaeological evidence comes from three areas: the east Brazil highlands, the Andean highlands and southern Patagonia. In the caves of Lagoa Santa in the east Brazil highlands were found bones of extinct animals and human remains of a physical type different from the modern Indians. Here again, association with extinct animals does not necessarily indicate extreme age. The human skulls are, however, lower and longer than modern types. These same characteristics were found in skull material from another cave in the same region, and at Punin in highland Ecuador.

Other early campsites have been found in several parts of the Andes. In southern Patagonia cave sites at Palli Aike and Fell's yielded stratified remains from the time of the early hunters until the historic period. Material from shell middens in southern Tierra del Fuego and on the north coast of Chile indicate an early occupation by fishing groups. An estimation of the age of the Patagonian material, based on the rise of land level in relation to the sea, gives an age of eighteen hundred years for the earliest shell midden occupation. The Carbon 14 date for Indian hearths in Fell's Cave is eighty-five hundred years ago. From this we can conclude that the first migrants must have reached the South American continent considerably earlier.

The sites we have just described give us the picture of the earliest known New World cultural material. Dated by geological methods, they cover the period from roughly fifteen thousand years ago to five or six thousand years ago. In a few instances the record suggests connections with more recent material but on the whole there is still a gap in our information after about 5000 B.C. The next date which seems reasonable to assign to archaeological material falls somewhere around 1000 B.C. This is arrived at not by geological dating but from archaeological records. This record for many parts of North and South America runs back more or less consecutively from the present. The details of these sequences will be considered later. Suffice it to say here that on the basis of this material archaeologists estimate that the earliest development of the cultures in these sequences must have begun about two or three thousand years ago. This leaves us with a gap between the end of the earliest material, about 5000 B.C., and the onset of this new period about 1000 B.C. This interval will some day be filled in. We may find that our dating is at fault. Perhaps the dates of the older material are too early and the recent material too late, creating a false gap. Perhaps we will find more exact evidence for dating the extinction of the animal species found associated with the earliest human remains. Or, perhaps, additional archaeological discoveries will extend

the recent record back in time, closing the gap from this end.

During this interval there must have been expansion of population, movements of people, and diffusion of culture traits within the New World. There may also have been some movement of people and of cultural material from Asia. We know this from the distribution of culture traits existing after the end of this gap. We find that certain simple elements of culture were almost universally distributed throughout the New World. These include: pressure flaking, grinding of stone, bone and horn, hafting of tools, firemaking, weaving or plaiting of baskets, mats, traps and weirs, projectile points used with either a spear thrower or a bow, the domesticated dog. Some of these traits are known from Folsom finds but others do not leave preservable remains to tell us how old they are. Because they are all traits characteristic of late Paleolithic and Mesolithic times in Europe and Asia, they may have been brought by migration or learned through contact across the Bering Strait. They may have reached the New World at one time or over a long period of time. Whatever their age or provenience they seem to be the common basis of the native New World cultures.

This set of material traits is nearly paralleled in distribution and presumptive age by another set consisting of social and religious institutions. Such traits leave, of course, no material remains but their wide distribution among historic Indian groups in both hemispheres suggests a long history. Such traits are: small hordes of kinsmen claiming the use of a tract of land; belief in magic and supernatural powers which are used sometimes for evil; crisis rites including ceremonies performed on such occasions as birth, puberty, death. These traits, like the set of material traits, may have reached the New World at one time or over a long period. Some may have been present by Folsom times or they may have reached the New World during the gap which followed the Folsom period and about which we know so little.

Areas of Indian Culture before the Conquest.—By the time the first Europeans reached the New World, the native people had spread across both continents. The hundreds of groups in which they lived fall into several areas of fairly uniform culture, and can be described and understood best in terms of these area settings. There are some differences of opinion among anthropologists as to the exact number of areas and the particular groupings in which the various tribes fall. But, on the whole, the disagreement concerns the smallest subdivisions within the subareas. It is generally accepted that the New World can be described in terms of ten large areas which can be divided at least once, giving twenty, or more, subareas.

The cultural areas into which the Indian tribes can be divided correspond closely to natural areas considered in ecological terms. This relation between cultural and natural areas does not imply that cultures are produced entirely by their environment. However, once established in an environment a culture tends to be stabilized and limited by that environment. Of the various aspects of environment (climate, terrain, altitude, fauna, vegetation) which affect culture, vegetation is perhaps the most important. There is a close correspondence between the cultural and vegetation areas in North and South America.

In North America there are six basic culture areas: Meso-American, Southwest, Intermediate (California and Intermountain), Northwest Coast, Eastern-Northern, and Arctic Coast. In South America there are four: Andean, Circum-Caribbean, Tropical Forest, and Marginal. Each of these areas is divisible into two or more subareas. The division of the New World into two continental areas creates a false impression of independent growth. Actually, the Meso-American and Andean areas together form a bicontinental core of development. By the 15th century when the Caucasians reached the New World, these two areas constituted a peak of development far ahead of any other areas in density of population, advancement of arts, political development and wealth. Archaeological evidence from these areas indicates that at the earliest known stages (some centuries before Christ), they were already far advanced. They were, in fact, already developed to a point which was never reached in many other areas.

This same circum-Isthmian region is the place of origin of native American cultivated plants. The most important of these, beans and maize could also be grown in more temperate latitudes. With the diffusion of these plants to areas outside their point of origin, it seems likely that other traits of culture would have spread. Some of the results of this occurrence will be seen in the following description of the culture areas. These will be given from the Andean and Meso-American areas outward for each of the two continents.

SOUTH AMERICAN CULTURE AREAS

Setting.—The South American continent is divisible into three major topographic zones:

(1) the Andean region stretching along the Pacific Coast from Colombia to southern Chile; (2) the Tropical Forest area from the eastern slopes of the Andes across the valleys of the Amazon and the rivers of the Guianas, and including the eastern hill and coast area of Brazil; (3) the Tropical and Temperate Plains area stretching from Brazil to Tierra del Fuego. A fourth area, of interest as a cultural entity, is somewhat peripheral to continental South America. This is the Circum-Caribbean area which includes northern South America, all the West Indies, and Central America as far as the present Guatemalan border. The relation of this area to both the North and South American continents is complex and will be described in a later paragraph.

Race.—The South American Indians belong to the American Indian race which is a subdivision of the Mongoloid stock. The characteristics common to all South American Indians are straight, black hair, brown skin and brown eyes. On the basis of other physical characteristics they may be divided into four subtypes. The Indians of the Andean area are short of stature and brachycephalic (round-headed); the Indians living in the Tropical Forest area are short to medium in stature and mesocephalic (medium-headed); the Indians of the Matto Grosso, the Pampas, and Patagonia are tall and round-headed; the Indians of the highlands of Brazil, southern Chile and the Straits of Magellan are of medium to low stature and dolicocephalic (long-headed). The real significance of these differences in stature is not entirely clear. They may represent a difference in physical type, or they

may be the result of differences in the kinds of food eaten by the various groups. With regard to head shape, evidence of dolicocephalic traits was found in the earliest archaeological sites in Ecuador and southern Brazil. This early evidence plus the presence of this long-headed type in the furthest part of the continent suggest that this may have been the characteristic type of the earliest inhabitants of South America. The round-headed type may have developed from the earlier type or, more probably, represents a later, separate migration.

Language.—The Indians of South America spoke about 250 languages, which are classified into some 40 linguistic stocks. At the time of discovery, the number of people speaking any of these different languages varied greatly; some were spoken by only a few hundred people living in a small area, others were spoken by many tribes spread over huge areas. In the Andean area, the principal linguistic families, from south to north, were the Araucanian, Aymara, Quechua, and the Chibcha which extended into Central America. Most of the Indians of the tropical forest spoke languages of the Arawak, Carib, Tupi, Pano, and Tucano families. Arawak and Carib extended into the West Indies. The Indians of the open country from Brazil to Tierra del Fuego spoke, for the most part, languages of the Gé, Guaycuru, Puelche, and Tehuelche families. Some of this linguistic distribution occurred rather late, perhaps a few hundred years before the conquest. The expansion of the Inca Empire, for example, was responsible for the wide distribution of Quechua and the suppression of local languages. The Incas, however, never succeeded in suppressing the Araucanian-speaking people of northern Chile who, today, speak that language. Other languages such as Arawak, Carib, and Tupi were spread by extensive migrations.

Prehistory.—The earliest migrants into South America were nomadic people who lived by hunting, fishing and gathering wild foods. They were not very different from their ancestors who had crossed the Bering Strait from Asia into the New World. Like those ancestors, the early migrants into South America had no knowledge of agriculture, metals, or pottery. Aside from such areas as the jungles of the Ecuadorian and Colombian coasts and of the Amazon, the extreme desert of northern Chile and the areas of the Argentine suitable only for the later herders and farmers, the South American continent provided extensive areas favorable for these early nomads. The highlands of the Andean mountains supplied the game and wild food suited to their needs. Because the main valleys of the Andes run north and south, a continuous southward migration was possible and doubtless accounted for the main flow of settlers. Some early groups also found suitable fishing sites along the Pacific coast. Others spread eastward from the Andean area into the east Brazil highlands, which also offered good hunting. Further country suitable for hunting and gathering wild foods was found in the Pampas and Patagonia, and on into Tierra del Fuego. Some of these hunting and gathering people were still living in the east Brazil highlands, the Pampas, Patagonia, and the Chilean archipelago at the time of the European conquest.

The earliest archaeological material from South America consists of two kinds: human skeletal material found associated with extinct

fauna, and cultural remains found at campsites and fishing sites.

In 1835 about 800 caves in the Lagoa Santa area of the east Brazil highlands were explored by T. W. Lund, a Danish naturalist. The material from these caves consisted of bones of extinct fauna and some human skeletal material. The human material was especially interesting because it represented a physical type somewhat different from the modern Indians of that area. Material excavated from the Confinis Cave in the same area corroborates the earlier discoveries. At Confinis a human skeleton and parts of a fossil horse and of mastodon were found buried about two meters deep and sealed in by fallen debris. As has been mentioned in a previous paragraph, the exact age of extinction of New World fauna is uncertain but it does not necessarily imply great antiquity. In 1923 another fossilized human skull was found indirectly associated with extinct fauna in volcanic ash beds at Punin in the highland of Ecuador. The human skull material from these three areas, Lagoa Santa, Confinis, and Punin are of a similar long, low type. Early campsites have been found in several places in the Andes. These contain stone tools such as points and scrapers. Two early cavesites, in southern Patagonia, Palli Aike and Fell's, (with a Carbon 14 age of eighty-five hundred years), contained stratified deposits of material ranging in age from the time of the early hunters up to the occupation by the historic Ona. Fishing sites have been excavated on the shores of southern Tierra del Fuego, the Chilean archipelago and the coasts of Chile and Peru. The oldest known shell midden age is about eighteen hundred years.

The story of the succeeding migrations and culture changes is still only incompletely known. Migrants probably continued to reach South America because the later physical type is short and round-headed. The one area from which we do have a fairly continuous history is the north coast of Peru. Evidence from buried villages indicates that the fishing people who lived here were raising cotton, beans, and gourds as early as 2000 B.C., although they did not make pottery or raise corn or manioc at that time. In this same area evidence is found of such subsequent developments as the making of pottery, domestication of the llama, cultivation of corn, manioc and other plants, the introduction of weaving, the use of metals, irrigation and the whole elaborate growth of art, architecture and a complex political organization.

Domestication of plants and of wild animals was of great importance in the development of New World cultures. With the possible exception of gourd and cotton, the domesticated plants of the New World are indigenous species, unrelated to plants of the Old World. Recent botanical investigations point to the conclusion that plants such as maize, sweet potatoes, peppers, peanuts, manioc and tobacco, which are each represented by a single species, are of South American origin. The lowland country, possibly the grassland of Paraguay and Bolivia seems a likely center of origin. Because maize became such an important crop in many parts of the New World, its domestication is of particular interest. It seems probable that maize is South American in origin because that is where the greatest number and most differentiated varieties of maize are found. Specifically, it seems probable that maize

was developed from pod corn and that this development took place around Paraguay.

Other plants such as squash, beans, tomatoes, and cotton, which are represented by two or more species, may have been domesticated independently in South America and in Central America. Still other plants such as coca, the white potato, quinoa, and oca seem to be Andean in origin. Some of these plants achieved a wide distribution in the New World. But such an achievement would not have required any great span of time. Botanists consider that the whole process of domestication could have been completed in a few thousand years. We know that the Indians of the Peruvian coast, for example, had domesticated plants before they made pottery, probably about 2000 B.C. This would allow ample time beforehand for the process of domestication and time afterwards for the wide distribution of these plants.

The dog was the only domesticated animal known widely over South America. A few animals, such as the guinea pig and the llama and alpaca were domesticated in the Andean area. The guinea pig was known in many parts of the Andes but was not a very important animal. The llama and alpaca, probably domesticated at an early date from their wild relatives the guanaco and vicuña, were restricted to the high grasslands of the Central Andes and parts of northwestern Argentina. They were useful for transportation and as a source of wool, meat, hides, fertilizer, fuel and of bone for tools.

Cultures.—South American Indians can be grouped into four areas of native culture: (1) Andean, (2) Circum-Caribbean, (3) Tropical Forest, (4) Marginal.

Andean.—In terms of cultural development the Andean area consisted of three subareas, the central area of high culture flanked by the North and South Andean areas. The basic pattern common to the whole area at the time of the Spanish Conquest, was one of skillful farming which included the use of fertilizers and the building of irrigation ditches and elaborate agricultural terraces. Corn, beans, squash, potatoes, manioc, peanuts and peppers were the principal food crops. Cotton, coca and tobacco were also grown. The llama and alpaca served, in the central highlands, as pack animals and also as an important additional source of meat, and of wool and bone. Guinea pigs were widely raised for food.

The Andean farmers were also skillful craftsmen. They distinguished between two types of products, one for utilitarian purposes, and one, which was more elaborately and carefully made, for ceremonial or mortuary purposes. The pottery, weaving, and metal work showed many different styles at different times and places but was of a uniformly very high level of skill and beauty. The more skilled craft work was done by specialists, while the utilitarian wares were produced by each family. In contrast to most of the rest of South America the Andean people were sedentary and lived in centers of fairly dense population. Houses in the Central Andes were constructed of stone and adobe. In Colombia and Ecuador frame houses with thatched roofs were lined with stone or clay. The Auracians in Chile built plank houses. In all these localities each household consisted of closely related families and a village was made up of several such households. Each village had its own chief and

was usually also a religious unit. During long periods of their history these villages were united into larger political units. This development reached its height under the Inca who created a political empire extending from Ecuador to Chile.

The pattern of this Andean farmer culture was fairly uniform in the Central Andes over a long period of time. From extensive archaeological work in this area it is possible to reconstruct the development from very early beginnings to its greatest height under the Inca Empire shortly before the Spanish Conquest. In the Chicama and Viru valleys on the north coast of Peru there is evidence of an agricultural people who did not yet make pottery. This material dates from about 2000 B.C. and may well be the earliest New World culture which practised farming but lacked pottery. The subsequent cultural development had, of course, many local variations but was also marked by a surprising degree of uniformity. Three successive waves of cultural influence spread over most of the area. These are named Chavin, Tiahuanaco, and Inca, and may be dated respectively at about A.D. 1, 1000, and 1450. Each of these cultures is represented by stylistic differences in pottery, textiles, metalwork, and building construction.

The Incas, who were the last in this sequence, were originally a small tribe inhabiting Cuzco, a mountain valley in southern Peru. By means of a series of military victories, they conquered the tribes around them until they controlled an empire of six million subjects living in a territory which extended three thousand miles from Colombia to Central Chile. The Incas constituted the ruling class in their empire and established their capital at Cuzco. The characteristic enabling the Incas to build up and then maintain this huge empire was their ability to organize and administer. The state consisted of administrative units beginning with the empire itself and going down through the provinces and districts to the villages. The emperor was at the head of the officers administering these units and his power was absolute. He was, in fact, thought to rule by divine right because he was descended from the Sun, the chief Inca deity. All military and governmental officials were chosen from among the descendants of past emperors, concentrating the power in a small group.

When the Incas conquered a new tribe, much of the local culture was left undisturbed, but the group was incorporated into the empire and required to assume the cult of the sun. Quechua, the language of the Incas, was also the official language of the empire and replaced the local languages. The local leaders were absorbed into the administrative structure of the government. The farmland was divided into three parts for the support of the state, the Inca priesthood and the people. Everyone was required to work on these lands and also on public works such as roads. To insure loyalty and to spread their culture and the Quechua language, the Incas frequently transplanted thousands of people from one district to another. This was sometimes done to equalize population distribution and sometimes to minimize dissatisfaction. All aspects of their subjects' lives were rigidly controlled by the ruling Incas. There was a minimum of individual, personal liberty. However, all government officials were held responsible for the well-being of the people under them.

The communication necessary to maintain such an intricate administrative machinery was made possible by an elaborate system of roads. There were two roads stretching the length of the empire. One lay along the coast. The other, highland, road was paved with stones, ascended steep gradients by means of steps, and crossed rivers and gorges by means of suspension bridges up to 300 feet long. These two main arteries were connected by lateral roads which tied the whole kingdom together. Posthouses, storehouses, and inns were built at frequent intervals along these roads. The posthouses were only two or three miles apart so that a system of couriers could carry messages from one to the next. The storehouses and inns were, perhaps, fifteen miles apart and were for the convenience of official travelers as well as for the storage of food and arms. Another development which facilitated the administration of the empire was the Inca *quipu*. This was a counting device operated on a principle similar to that of the abacus. The *quipu* consisted of a thick cord from which hung knotted strings of different colors. The number and position of the knots represented numbers in a decimal system. The colors of the strings represented different kinds of objects. This device was used to keep statistical records of military, economic, and population matters. The Inca never developed any system of writing but the *quipu* enabled them to keep records of a limited variety.

Inca culture was really the culmination of developments which had been going on for a thousand years. Some of these reached new heights under the Incas who excelled in engineering and architectural skills. Besides the roads, which have already been mentioned, the Incas built elaborate systems of irrigation ditches and agricultural terraces. The ditches were sometimes cut through solid rock or carried along sheer cliffs on stone aqueducts. The stonefaced agricultural terraces covered entire slopes from the valley floor to the summit. The Incas also accomplished remarkable architectural feats. Their houses were simple stone or adobe structures with roofs of grass thatch. Their public buildings, on the other hand, were massive structures built with great skill. The construction was of huge dressed stones, laid without mortar and fitted with greatest exactness. These stones were sometimes cut into polygonal shapes and the edges were beveled. Among these buildings were palaces, temples and fortresses. The enormously imposing structures in the Cuzco area such as the fortress of Sacsahuaman, the temple at Ollantaytambo and some of the buildings at Machu Pichu date from the late Inca times and were the final examples of this development. The Incas were competent potters and weavers and did skillful work in metals, but they did not achieve such impressive results in these crafts as they did in the engineering and architecture. Their weaving and pottery were, in fact, less imaginative than were those of earlier periods.

When Francisco Pizarro, leading the Spanish invaders, arrived in 1532 he was able to conquer the Inca Empire with surprising ease. This conquest was facilitated by a struggle which was taking place within the Inca dynasty. Pizarro capitalized on this state of civil war and, after the two Inca claimants to the throne were killed, he was able to take over control of the whole empire.

The Northern Andean subarea included Ecuador and highland Colombia. The people here were also sedentary farmers but their culture was in no way as highly developed as that of the Central Andes. Their greatest skill was in metal-working which was like that of the people of the Isthmus of Panama. The Chibcha at the northern extremity of this area had an elaborate political development with autocratic hereditary rulers.

The South Andean area included southernmost Peru, the north Chilean desert, a corner of northwest Argentina and a high, fertile stretch of Chile. The Calchaqui or Diaguita of northwest Argentina show some influence from the Tiahuanaco and Inca periods of the Central Andes. The Chiriguano came up from the area where Peru, the Chaco, and the Tropical Forest areas meet to challenge the Inca on their eastern border and were in turn influenced by Inca culture. The Araucanian farmers of central Chile seem to have been fairly independent of Inca influence and to have resisted, also, the Spaniards.

Circum-Caribbean.—The part of this area lying along northern South America, the Isthmus of Panama and up to the Guatemalan border was occupied by Chibcha-speaking peoples. The cultural development of these peoples was much less elaborate than in the areas to the north and south of them. The Chibcha were agriculturalists; they constructed irrigation systems and raised maize, potatoes, manioc, beans, and squashes. They also raised cotton and did fine weaving. Their houses were built of wattle and plaster, and they also built roads and suspension bridges. Their greatest handwork was of gold, in which they excelled, and which they traded as far away as the Maya, perhaps even beyond there to Mexico. The Chibcha lived in palisaded villages organized into a compact political system. Taxes or tribute were exacted in gold or cloth, and they also had markets and a kind of currency. Chibcha religion involved many sacrifices including human sacrifices to the sun. The religious leaders formed an organized priesthood with a leader. The fringes of this Isthmian culture extended into the highlands of Venezuela and, on the south, as far as the Inca area in Ecuador.

The island part of this Circum-Caribbean area was occupied by Arawak and Carib-speaking peoples. The orientation of their culture was toward the South American mainland. The earliest, pre-agricultural culture survived longest in western Cuba and the Bahamas. A Taino-speaking people, related to the Arawak in South America, overran this early population in most of the remaining islands. The place of highest development was in Puerto Rico and Haiti. Following the Taino came the Carib-speaking people, also from the South American mainland. And, lastly, the Spaniards arrived, and the native cultures disappeared so rapidly that our knowledge of them is very meagre.

Tropical Forest.—This area included the huge expanse of the Amazon Valley, the upper Orinoco, the valleys of the Guianas rivers and also the hill ranges and coast area of eastern Brazil. The river areas were true rain forest where travel was primarily by canoe, metal was completely absent and stone was very scarce. The hill and coast area was scrub forest. Food was actually fairly scant in this whole area so the people lived thinly scattered. Fish were

an important source of food and they were caught in nets and traps, shot with arrows, or stupefied with poison. Hunting was done with bows and arrows and blowguns with poison darts. Practically all tribes farmed. The most important crop was cassava, although maize, squashes, beans, pineapples, and cotton were also raised. Manioc meal and tapioca were obtained from the cassava by means of graters, squeezers, and roasters, the poisonous juice being expelled by means of a most ingenious basketry press. One use of the cotton was in making hammocks, which seem to have been invented in this area. There was some pottery-making and weaving of cloth. Enormous dwellings housing a whole village of related families were made of thatch and supported on posts.

Although the dense vegetation and the tropical nature of this jungle area prevented the penetration of the aggressive Inca into it, the tropical forest tribes themselves moved about on the rivers quite easily and frequently. Most of their migrations were in search of new lands to farm. The wide scatter of different linguistic groups in this area reflects the frequency of migrations. Several villages speaking one dialect constituted a tribe but they had no formal organization. The villages were situated close to the rivers. Each had a chief and a council of male adults. Religious life was simple and medicine men carried out curing rites.

The thickness of the jungle vegetation has impeded archaeological investigation of the early history of much of this area. The Lagoa Santa and Confins caves in the east Brazil highlands have already been mentioned in connection with the discussion of early migrants. It is possible that the coastal shell middens will yield some information. On Marajo Island in the mouth of the Amazon River excellent, pre-Columbian pottery has been found. This pottery is modeled, incised and painted and certainly represents the finest workmanship of any kind east of the Andes.

Marginal Area.—The long area extending from the east Brazil highlands across the Chaco to the southern tip of South America was made up of two subareas. The southern part was occupied right up to the conquest by nomadic hunting tribes whose life was doubtless similar to that of the earliest nomadic hunters. In this area lived the Alacaluf and Yahgan Indians of the Chilean archipelago, and the Ona and Tehuelche of Patagonia. These four tribes are the most primitive in the New World and compare, in this respect, with the Australian natives and the Bushmen of South Africa. The Alacaluf and Yahgan Indians subsisted on the marine life of the archipelago, hunting seals and other sea mammals, gathering shellfish and fishing. The Ona and Tehuelche hunted land animals and gathered wild plants. Both groups had simple, portable skin shelters which they erected on stick frames. Their clothing consisted of capes, mocassins, and sometimes leggings which the Ona and Tehuelche made from guanaco skin while the Alacaluf and Yahgan used sealskins. All four tribes greased their bodies for protection against the cold, which was very severe. Both the mainland and the archipelago Indians had the simplest tools and utensils of bone, shell, stone and bark. The canoes of the Alacaluf and Yahgan were made of strips of beech bark sewn together and held in place by split saplings.

The middle part of this marginal area was the Chaco, an open plain where the Puelche, Que-randi, and Charrua tribes lived. These tribes were fairly large and warlike. Their culture was not quite so simple as that of their more isolated neighbors to the south. They made some use of wood for utensils, ground seeds in stone mortars and, along the borders of this area, had acquired some pottery from their northern neighbors. Upon the arrival of Europeans and more particularly with the introduction of the horse into this area, these Indians readapted their culture and developed a life similar in many superficial respects to that of the Plains Indians of North America.

The Gê-speaking tribes are the northernmost group in the Marginal area and occupy the savanna and scrub country of east Brazil. Hunting, gathering, and fishing are important with the addition of some farming of sweet potatoes and yams. Their technology is also fairly simple although a few tribes make pottery. These tribes have, however, a rather complex social and ritual organization. Some of these Indians live in villages with a population of nearly three hundred. There is little or no intervillage organization. Each village is usually divided in halves for the regulation of marriage, performance of ceremonials and for competitive games. There are also ritual societies for the performance of ceremonials.

Very little is known of the prehistory of this whole Marginal area. Nothing has been found which would indicate any previous higher development. It is assumed that the simple culture in this area is a survival of the early cultural poverty.

NORTH AMERICAN CULTURE AREAS

Setting.—The North American continent includes a great range of topographic zones: Arctic, Mountain, Plains, Prairie, Woodland, Desert Plateau, and Jungle. In terms of native cultures, these topographic zones combine into six culture areas each of which may have several subareas: (1) the Meso-American area covering the region from central Honduras and El Salvador to northern Mexico; (2) the Southwestern area covering the desert and plateau regions of New Mexico and Arizona; (3) the Intermediate area including California and the intermountain region; (4) the Northwest coast area from Oregon north to Alaska; (5) the Arctic area; (6) the huge remaining area of Canada and the United States east of the Rocky Mountains constituting the Eastern-Northern area.

Race.—The Indians of North America, with the exception of the Eskimo, belong to the American Indian race which is a subdivision of the Mongoloid stock. The Eskimo are classified as Arctic Mongoloid because they show less admixture of non-Mongoloid stocks. Setting aside the Eskimo, the remaining North American Indians show some variation in head form and stature. The tribes of the Plains area are generally taller and more long-headed than, for example, the Indians of the Southwest and Meso-America. Here, as in South America, the differences in stature may be due to diet as well as to physical type.

Language.—There were 40 or more linguistic families in North America, some of which were spread over huge areas, others spoken by a few hundred people. The principal families, in

terms of numbers and cultural importance, and the well-known tribes representing these families were: (1) Eskimo, spoken along the Arctic coast from Alaska to Greenland; (2) Athabaskan, spoken by the Beaver, Dogrib, Yellow Knives, Carrier and others in the northwest interior of Canada and Alaska, by the Hupa, Kato and others in California and Oregon, and by the Navajo and Apache in Arizona and New Mexico; (3) Algonquian, spoken by the Arapaho, Cheyenne, and Blackfoot of the Plains area, by the Sauk and Fox, Cree, Menomini, Shawnee, Ojibway, Delaware, Kickapoo, Miami and others in the great expanse of eastern Canada, the area around and south of the Great Lakes, the New England and Middle Atlantic states area; (4) Iroquois, spoken by the Cherokee, Huron, Erie, Mohawk, and Seneca and others in the area of New York, Pennsylvania, Ohio, and adjacent territory; (5) Siouan, spoken by such Plains tribes as the Dakota, Assiniboin, Omaha, Osage, Hidatsa and Crow; (6) Muskogean, spoken in the southeastern area by Choctaw, Chickasaw, Creek, Seminole, Natchez, and others; (7) Uto-Aztecan spoken by the Aztec, Seri, Yaqui, and others in Mexico, by the Hopi and Pima in the Southwest, and by the Ute, Comanche, Shoshone and others from Wyoming to southern California and across to Texas; (8) Maya, spoken in Guatemala and Yucatan, plus a small area further north in the Mexican State of Vera Cruz.

Prehistory.—The oldest evidence of North American prehistory was quite thoroughly described in earlier paragraphs. Here we will summarize such material as is necessary for our subsequent description of the native cultures which developed from this early base. The first migrants probably reached the North American continent about eleven thousand years ago fanning out slowly over the two New World continents wherever they found wild game, wild plants, and fish. The earliest known cultural materials in North America are from the Sandia Cave in New Mexico; the somewhat later Folsom people who were present in the Southwest by 8000 B.C., and of the Cochise people somewhat later still. Evidence of the persistence of the Cochise culture and the gradual addition to it of farming and pottery-making fill in the local, southern Arizona story up to the Christian era. At this point these early developments tie in with the known sequences of cultures which have been carried back from the historic period to the early years of the Christian era in Meso-America, the Southwest, and east of the Mississippi.

Cultures.—North America can be divided into six areas of native culture: (1) Meso-American, (2) Southwest, (3) Intermediate, (4) Northwest coast, (5) Arctic, and (6) Eastern-Northern.

Meso-American.—This area includes Mexico, except for its most northern part, British Honduras, Guatemala, and the adjacent parts of Honduras and El Salvador. For many years it was believed that the several cultures which reached a high degree of development in this area did so independently of each other and with only their most primitive phases in common. Recent archaeological work indicates that there was contact over practically all of this area during most of its history. Several culture patterns which were interrelated in origin became distinct, local developments from a common basis. These local developments will be considered from south to north.

The Maya people fall into two groups: the Lowland Maya lived in Yucatan, British Honduras, and the Peten district of Guatemala. They spoke Maya and such closely related dialects as Chol, Chorti, and Chontal. The Highland Maya occupied upland Guatemala and spoke the Quiche, Cakchiquel, and Mani dialects of Maya.

An erroneous early theory maintained that the Maya had domesticated maize and were the first American farmers. More recent botanical evidence indicates that maize is probably South American in origin. This information is of interest because it was assumed for many years that the elaborate Maya artistic and intellectual development went hand in hand with their skill as agriculturalists. Actually, plant domestication probably took place two thousand years before the great rise of Maya culture and several thousand miles further south.

The earliest period known for the Lowland Maya is called Formative and is based on pottery-types and other refuse-heap material from sites in the Peten district of Guatemala. During this period the basic Mayan astronomy, writing and mathematics were being developed. These intellectual achievements, the Maya calendar which is based on them, and the magnificent artistic expression reached their height during the classic period. The beginning of this period is set by the earliest known date of the Maya calendar—317 A.D. The calendar, based on centuries of astronomical observations and mathematical calculations, was exceedingly accurate. Calendrical inscriptions were used primarily to record ceremonial dates and are found inscribed on stone monuments in all parts of the Lowland Maya area. The Maya were also very skillful potters, lapidaries, sculptors, painters and architects, as is attested by the contents of tombs and by the buildings found in the Peten district and in Yucatan. They also built ball courts for the playing of a ritualistic game with a rubber ball. These skills were doubtless practiced by specialists. The average Mayan was a farmer living in a wood and thatch house near his field. Maize, beans, squash, pumpkins, sweet potatoes, avocados, and cacao were the food crops, while cotton and hemp were also raised. The farming technique required burning and slashing the jungle growth. New fields had to be cleared often because the jungle grass grew so luxuriantly in a field cleared of brush. The domesticated animals included turkeys, dogs, and bees. Wild pig and deer were hunted with blowgun, bow and arrow, poisoned darts or traps. The Maya lived in independent city-states each of which was a unit and had its own religious center. Each city-state was ruled by its priests.

The Maya classical period came to an end in the early 10th century. The late period, which followed, was characterized by a decline in Maya culture and the abandonment of their great cities in the Peten. They continued to occupy some of their cities in Yucatan where there was some local persistence of Maya culture but also a strong influence from the Toltec people of the Valley of Mexico on art styles and religious cults. Warfare among the city-states also developed. It was at the end of this period that the Spaniards arrived, conquering the Maya in 1540.

The Highland Maya never achieved the rich development of the Lowland group. They did have the calendar but their artistic development was not spectacular.

During the years in which Maya culture was growing and declining other developments were taking place to the northwest in the Valley of Mexico. These developments used to be described in the sequence Archaic, Toltec, and Aztec. Since the earlier 1930's this overly-simple sequence has been changed. The Archaic was clearly a well-developed pattern and so was renamed middle, leaving the term "early" for an, as yet, unidentified period. The subsequent periods are called Teotihuacan, Toltec, Chichimec, and Aztec.

The middle period is represented as gradually developing around the old Lake Texcoco which then was at a higher level. Farming, pottery-making and weaving were already practiced and the people lived in villages. They made large numbers of baked clay figurines, which evidently were of religious significance. Some middle period sites lie under a lava flow, leading a few people to assign a great antiquity to them. Geologists, however, do not agree. It seems much more likely that these sites fall somewhere between 350 B.C. and the year zero.

The Teotihuacan period overlapped at its early end with the middle. The fully developed Teotihuacan period was most impressive. The huge Pyramid of the Sun (700 feet at the base and over 200 feet high) dominates an enormous ceremonial center whose buildings are decorated with sculptures and murals. Teotihuacan culture seems to have reached its highest development about A.D. 500. The influence of the Teotihuacan style, probably spread by means of trade, has been traced to the coast, to the Monte Alban site in Oaxaca, to a site near Guatemala City, and to a classic Maya site in the Peten. It was once thought that the Toltec people had built Teotihuacan but, actually, they established their capital near Tula several centuries later. We have already noted their influence on the Maya of Yucatan. Some of the history from Toltec times on is known from records kept in picture writing. These records list kings' names and describe the defeats and victories of some of the cities from the ninth century to the Spanish Conquest. The Toltecs were displaced by the warlike Chichimecs from the north, and for some centuries there was warfare among the cities of the valley.

In the 13th century another invading tribe, the Aztecs, descended on the valley from the north. By 1324 they had established their capital at Tenochtitlan and, by gradually strengthening their position through alliances and conquests, finally dominated an empire extending to the Isthmus of Tehuantepec. Warfare was an important aspect of Aztec life and played a part in their religion, their social organization and their economy. All Aztec conquests were for the sake of obtaining tribute for their treasury and prisoners for sacrifices in their religious ceremonies. The Aztecs were primarily farmers raising maize, beans, squashes, sweet potatoes, tomatoes and chili peppers. They also raised cotton and maguey for the fibers. They had domesticated dogs and turkeys, caught fish with hooks, nets and weirs, and hunted deer and wild fowl with bow and arrow, spear thrower, nets and darts. In addition to weaving, the Aztec men did excellent work in wood, stone, masonry, metal and pottery. Some of these crafts were organized into hereditary guilds. The craftsmen traded their wares at markets or sold them for cotton cloth, cocoa beans or copper axe blades

which were considered to be a kind of currency. All these wares were also carried long distances by itinerant merchants who traded them with other tribes. Their houses were of simple size and construction. They also built large earth pyramids, faced with sculptured masonry, which were bases for altars and temples. Their capital, Tenochtitlan, was on an island connected with the mainland by causeways and protected from attack by drawbridges.

Aztec society was divided into four classes and was ruled by a king and his advisers, a council of representatives from the 20 clans which included the majority of the people. The king was also the war chief. The religious life of these people was conducted by priests, and consisted of a great many ceremonies pertaining to agriculture and warfare. The ceremonies were performed according to a ritualistic calendar which consisted of two hundred and sixty days divided into thirteen "months" of four "weeks" each, the week having five days. The Aztec also had a solar calendar of three hundred sixty-five days divided into eighteen "months" of twenty days each plus five supplementary days. Each division of both calendars had its own god who was considered to influence the events of that day. Before undertaking anything important, an Aztec always consulted the calendars to determine the appropriateness of the day. Another matter of interest in Aztec life was a game with religious and mystical importance played with a rubber ball in a large stone court.

In 1519 the Spanish soldiers landed at Vera Cruz with their leader Hernando Cortes. For two years the Aztecs succeeded in resisting them. Finally, Montezuma II (1480-1520) was imprisoned, hundreds of Aztecs were massacred, and the Spaniards, aided by reinforcements, conquered the Aztecs.

Outside these areas of highest development in Meso-America lay the Huastec, Totonac, and Olmec people of the Atlantic coast and lowland, the Zapotec of Oaxaca, and the Otomi and Tarascans to north and west of the Valley of Mexico. Of these, the most is known about the Zapotec, who seem to have had a distinctive culture touched by both Maya and Valley of Mexico influences. From a late period at the site of Monte Alban comes the famous gold jewelry made by the Mixtecs who conquered the Zapotecs.

To the north, across the rest of Mexico, lived Indian groups who had some characteristics of Meso-American culture but none of its highest developments. Farming was practiced in the western half and good pottery and some stone construction were made all over but neither the calendar nor picture writing were present. The archaeology of this area is not yet well known. It is, however, potentially very important because across it flowed the cultural influences which, we will presently see, reached the southwest from the high cultures of Meso-America.

Southwestern.—This area includes part of northern Mexico, all of New Mexico and Arizona, and the southern part of Colorado and Utah. Much of this area is very dry, with a rainfall of 10-15 inches a year. There are also high plateaus, mountains and mountain valleys, which receive 22-40 inches a year. The Southwestern area has been a particularly rich one for anthropological research. The country lends itself to archaeological reconnaissance and excavation because of its openness and its arid climate

which affords excellent conditions for preservation. In addition, it is the first area for which any precise system of archaeological dating was developed. This technique, known as dendrochronology, is based on a comparison of the growth rings of trees. By a careful comparison of the rings on timbers and other wooden objects found in archaeological sites, with the rings on a master chart, dates for these sites are determined. This technique has carried dating back from the present to A.D. 11. As a result of these conditions, a fairly full story is known of the rich development of early cultures up to historic times. The main prehistoric Southwestern cultures were the Anasazi, the Hohokam, and the Mogollon. The Anasazi people (consisting of the early Basket Maker and their actual and cultural descendants, the Pueblo) lived on the plateau of northern Arizona and New Mexico. The Hohokam culture was parallel in time to the Anasazi, centered in the southern Arizona desert, and was ancestral to the present-day Pima and Papago of that area. The Mogollon culture centered in east central Arizona and west central New Mexico in mountainous country. It probably descended from the earlier Cochise culture.

The Anasazi culture sequence is made up of stages referred to as Basket Maker and Pueblo. It is not known just what preceded the Basket Makers. The earliest Basket Maker period dates from about 100-500 A.D. These people practiced agriculture but did not make pottery. As their name suggests, they wove many articles including baskets, bags, and sandals. They used the spear-thrower but did not have the bow and arrow. Their houses were temporary structures but they did line their food-storage pits with stone slabs which may have marked the historical beginning of their subsequent stone construction. A Modified Basket Maker period lasted from about 500-700. Turkeys had been domesticated and more varieties of maize introduced, and pottery-making was begun. Following this, the sequence of Pueblo development has been divided into five stages each a little richer and more complex than the one before. Pueblo I (700-900) had added the bow and arrow and cotton for cloth. Both were probably imports. Some masonry houses were built and a pottery decoration called corrugating was introduced. In the Pueblo II period (900-1050) rooms with common walls were built forming dwelling clusters so well-known for later years in this area. In Pueblo III (1050-1300) times, polychrome pottery decoration was begun. This was the period of the greatest development of masonry houses including such impressive and well-known sites as Mesa Verde and Chaco Canyon. Pottery-making and design also reached a high point in the Mimbres style. Pueblo IV (1300-1700) was a period of expansion and cultural development. By this time some of the present-day Pueblo towns were already occupied. It seems likely that the Pueblo ritual development, which was to become so elaborate, has its origin in this period. The Spaniards first reached the Southwest in 1540.

The villages of the historic Pueblo people, still lived in today, fall into three geographical groups: the Hopi (Walpi, Sichomovi, Hano [Tewa], Shipaulovi, Mishongnovi, Shungopovi, and Oraibi); Zuni (Zuni proper, Pescado, Nutria, and Oja Caliente); and the Rio Grande (Taos, Picuris, San Juan, Santa Clara, San

Ildefonso, Tesuque, Pojoaque, Nambe, Jemez, Pecos, Sandia, Isleta—all of which speak Tanoan languages; San Felipe, Cochiti, Santo Domingo, Santa Ana, Sia, Laguna, and Acoma—all speaking Keresan languages). Although there are differences among these three groups, they share such basic traits as dependence on maize and other cultivated foods; masonry construction; weaving on upright loom done by the men; cultivation of cotton; domestication of the turkey; common-wall houses; decorated pottery. These Pueblo people do some hunting including the deer and rabbit, and rabbitskin strips are woven into their clothing. They make basketry and do work in turquoise and metal which was unknown until introduced by the Spaniards. Pottery and such ceremonial paraphernalia as sand painted altars and masks are skillfully made and beautifully decorated.

Although differing still in detail, the Pueblo groups all have complex social groupings based on kinship relationships which are important in ceremonial and economic matters. Each village is also an independent unit which elects its own officers. The most elaborate flowering of Pueblo culture is in its ceremonial life. Ritualism is highly complex and includes elaborate masks, costumes, shrines, fetishes, dances and ritual acts. Many priests and religious societies are involved in carrying out the annual round of ceremonies some of the best-known of which are the Hopi snake dance, the numerous rain ceremonies and the masked dances of the kachinas.

Some of the initial stages and early development of this general pattern may be seen in the Pueblo IV period of the archaeological sequence. This same era saw the arrival of the Spaniards who first reached the Southwest in 1540 under the leadership of Coronado. The Indians were very hostile and because the Spaniards found no such treasure in this area as they had in Meso-America and Peru, it remained of interest to them primarily as a missionary field. It was not until 1598 that the Spanish succeeded in establishing a permanent occupancy. Even this was upset by the Pueblo Indians revolt in 1680, after which the Spaniards reestablished themselves by 1697. During this whole period from 1540-1697 a great dislocation of Pueblo populations took place and, whereas there had been seventy or more villages in 1540, by 1700 there were thirty or less. Despite prolonged contacts with the Spaniards and later with the Americans, the Pueblo Indians maintain their cultural identity and particularly their religious independence.

During the Pueblo IV period of Anasazi development, Athabascan-speaking people began coming down from the country to the north. These people had a hunting and gathering economy and, doubtless, a fairly simple cultural development. Some of these Athabascans, the present-day Apaches, moved south of the Pueblo area. Others, the Navajos (Navahos), settled near the Pueblo towns and learned such things as farming and weaving from the Pueblo people, although it should be noted that the Navajo women did the weaving instead of the men as among the Pueblos. The Navajos also took over a great many external aspects of Pueblo ceremonialism to which they gave their own meanings and emphasis. The Navajos may also have acquired the idea of clans, groups of relatives tracing their descent through either the male or female parent, from the Pueblos. The

basic pattern of Navajo social grouping remained, however, the same. They continued to live in large, thinly-scattered family groups which differ completely from the compact Pueblo village group. They also continued to depend on hunting and, after the Spaniards introduced sheep into the Southwest, they developed a greater dependence on herding than did the Pueblos. Like the Pueblos, the Navajos learned to work in silver from the Spaniards.

Nowhere else in the New World were native cultures as undisturbed by the arrival of the Whites as in some parts of this Southwestern area. An amazing proportion of native Pueblo, Navajo and Apache culture was able to survive first Spanish and then American conquest. As a result, these groups have been a rich source of information about and insight into the life and culture of non-European people.

It seems probable that the Hohokam culture of southern Arizona was a development from the very early Cochise culture which was described in an earlier section. As for its subsequent growth, there are no tree rings dates for the desert area of this Hohokam culture, but cross-ties show that its development paralleled the Basket Maker-Pueblo in time. Hohokam culture is described in four stages. Agriculture and pottery-making were known in the earliest stage; the earliest projectile points were for bow and arrow; they had no masonry construction but did build dug-out ball courts in which a ritual game, known as far south as the Maya, was played. The Hohokam also had pyrite mirrors and copper bells similar to some known in Mexico. The Hohokam built irrigation ditches and their early houses were of post and brush construction. During their final developmental period the Hohokam were considerably influenced by contact with the Pueblo III and IV people, and they adopted such traits as common-wall houses of packed earth which they substituted for Pueblo masonry. When the Spaniards first reached southern Arizona in the early part of the 16th century, they found the Pima and Papago Indians living a life similar to but simpler than the classic Hohokam pattern. Their scattered house, built in pit-house style; canal irrigation; pottery made by paddle and anvil and painted red-on-buff; effigy vessels; and cultivation of cotton are so similar to the Hohokam culture as to suggest descent from that group.

The Mogollon culture, like the early Hohokam, was probably a development out of the later stages of the Cochise culture. In the earliest Mogollon period, about the beginning of the Christian era, agriculture was already practiced and pottery was made. Recent evidence indicates that these people began cultivating corn several centuries earlier, at a time before they made pottery. From the 1st to 11th centuries A.D. Mogollon culture showed a fairly uniform pattern with minor variations and developments. After about 1050 there is evidence of strong Anasazi influence either through contact or invasion. There is also evidence of Hohokam influence.

South and west of this core area of Southwestern cultural development are the Uto-Aztecan- and Yuman-speaking people of Southern California and Sonora. Their culture seems to be a simple version of the Hohokam type. In this group belong the Yaqui, Maya, Yuma and Mohave.

Intermediate.—This region, consisting of California and the intermountain area between the Rockies and the coastal mountains, was one of slow development and little change. The California portion of it includes the southern California desert, the broad valley and pine-covered mountains of central California and the densely forested northern part of the state. The earliest cultural material known from California comes from campsites along Lake Mojave (Mohave) and Pinto Basin in the southern California desert and at Borax Lake in central California. The same problem obscures the dating of all of these sites. On geological grounds their age might be the last pluvial period which ended about ten thousand years ago. Or, it may have been during a wet period which occurred about 1000 B.C. The later date seems more acceptable on archaeological grounds. California culture was quite similar to the pre-farming, pre-pottery culture of the Basket Maker people and remained so even until recent times. Because the food supply was ample and the climate was mild, the density of population was high even in the parts of California which had a nonagricultural economy. Cultural development remained on a fairly simple level with evidence of considerable local specialization.

The most extensive cultural subarea was in central California. Here subsistence was based on fishing, hunting and the gathering of wild seeds, particularly of acorns. Acorns formed the chief vegetable food and were made into bread by a complex process which eliminated their tannic acid. The houses of this area were simple brush or tule shelters, or lean-to structures made of poles. These people made no pottery but did make excellent baskets which were used for carrying water and food, for storage, and for cooking by the stone-heating method. Social and political organizations were rudimentary in this area. The religious development was very simple, consisting of a few ceremonies. Shamanism was quite important. An interesting characteristic of this area is the large number of languages spoken in a small area.

To the south of this central area the basic pattern did not change much except for the important addition of pottery-making, and a great increase in linguistic homogeneity. This was an area of a large group of Yuman- and Shoshonean-speaking peoples. North of the central area the contrast was more striking and resemblances to the Northwest Coast area appeared. Fishing was of major importance, a variety of sea foods was consumed along the coast and salmon was the major food along the interior rivers. The construction of plank houses, the use of wood and elk horn for boxes and spoons, and also the increase in carving and decoration all suggest northern affiliations. The same was true of the more elaborate social organization characteristic of this subarea.

The Intermountain area consists of the Great Basin and the Columbia-Fraser Plateau regions. The Great Basin area, lying between the Rockies and the coastal ranges, was one of simple culture based on gathering wild foods. In this respect and also in basketry and house types, Great Basin culture resembled that of California. However, in terms of climate, vegetation and early development the Great Basin is closer to the Southwest. The seed-gathering, basket-making characteristics of the Great Basin are the

same as those described for the Basket Maker people of the early period in the Southwestern area. Lovelock Cave in central Nevada had an Atlatl-culture similar to Basket Maker. Material similar to the early Pueblo periods has been found as far into the Great Basin area as the Utah-Idaho line and the Nevada-California boundary. At an early period California, the Great Basin and the Southwest had common characteristics. The Southwest area surged ahead to a very full development. California managed a few cultural achievements. The Great Basin succeeded only in preserving its simple, early level.

Indians of the Columbia-Fraser Plateau region lived by hunting, salmon fishing and gathering berries and roots, especially the camas. The abundant salmon supply allowed a fairly dense population to live in the dry Middle Columbia region. Archaeological evidence of early cultures is lacking. The material from more recent times suggests that the fairly simple culture known for the early historic times had already been in existence for several centuries or, perhaps, longer. Pottery was not made in this area, but basketry was well developed and bags, mats and clothing were woven of bark fiber. Clothing was also made of deerskin. The largest social unit in the Plateau was the village. A number of villages were grouped together through sharing common dialect and customs, but there was no political structure to tie them together into a tribe.

About the year 1720, actually before the beginning of the historic period in this area, the southern and eastern Plateau tribes were strongly influenced by the adoption of the horse and other culture traits from the Indians of the Plains to the east.

Northwest Coast Area.—The river mouth, coastal and island region stretching from Oregon to the Alaskan border forms the Northwest Coast area, one of the most distinctive in the New World. Life in this area centered around fishing in rivers, in bays and other protected salt water areas, and also in the open sea. Archaeological material is spotty for this area. However, from a comparative study of the recent cultures it seems likely that the people first lived on the rivers and later on the beaches. Finally some, especially in the north, took to the sea and the archipelagos. The tribes included in this area fall into three groups from north to south: (1) the Tlingit, Haida, Tsimshian; (2) Bella Coola, Kwakiutl; (3) Nootka, Quinalt, Salish, Chinook, Tilamook, Yurok, Karok and Hupa. The most northerly groups showed the greatest cultural development. The Indians of this area were skillful and ingenious in their use of wood and in basketry and weaving. The Chilkat, a Tlingit tribe, wove blankets of goat hair by means of a warp suspended from a bar. All the tribes of this northern group built large dugout canoes and the houses of their winter villages were built of cedar timbers and split planks. They also made slat armor, boxes, and dishes of wood, and such ceremonial equipment as rattles and masks. They are, of course, renowned for their elaborately carved totem poles and house posts, covered with symbolic animal decorations. Their baskets were very well made. Pottery and metal-work were unknown. An interesting quality common to the techniques and style of decoration of all their work is its own force and its complete dissimilarity from anything around

it or, for that matter, from anything in the New World.

The Northwest coast tribes also had a distinctive development of economic, social, and ritual organization. There was a great emphasis first on accumulating and then on distributing wealth in the form of food, dentalium-shell currency, slaves, and sheets of native copper. This distribution took place at huge feasts called potlatches which were given to celebrate important events in the life of the individual, such as naming, coming of age, marriage, assuming chiefly office, and death. This Northwest Coast culture is clearly different from anything else in the New World. It was, of course, too far from the Meso-American high culture area to have been influenced by it. A number of Northwest Coast traits show resemblances to traits known in Asia. Slat armor is known from as far away as eastern Asia. The emphasis on wealth as a basis for social status and the use of carved masks are suggestive of Indonesia and western Oceania.

Eskimo Area.—The Eskimos live on the long stretch of Arctic coast from southern Alaska, across the whole of northern Canada to Newfoundland and on the west coast of Greenland. Linguistically, this entire area is covered by one family, also called Eskimo. In physical characteristics the Eskimos differ somewhat from the American Indian proper. They represent a branch of the primary Mongoloid stock known as the Arctic Mongoloid. Archaeological work in the Eskimo area has established a sequence of cultural developments but, so far, has not succeeded in establishing any definite dates. The earliest material is possibly from around 400 A.D. or may be as old as 1 A.D. Relationships with northeastern Asia were strong in the early stages while some later developments were local. Eskimo culture represents a fascinating and remarkable adaptation to an extreme environment. The coastal Eskimos live, for the most part, by hunting seals, walrus and whales. Inland, the caribou are hunted for their meat and fur, both by coastal groups who move inland during the summer months and by a few Eskimo groups which spend the entire year in the caribou country. Other specialties are river salmon fishing in some delta areas and large whale hunting at Point Barrow. The Eskimo's equipment is made from the few materials available. The seal is not only a source of meat but also provides skin for clothing and boats as well as blubber for cooking and heating fuel. The Eskimos make two kinds of houses, both quite small and compact. The winter house is made of rocks and slabs of stone. The snowhouse, or igloo, used on trips, is made of blocks of ice which, because they spiral into a dome, support each other. The igloo serves as a permanent winter house in areas of extreme cold where blowhole fishing is done through the ice of the frozen bays. In most parts of the Arctic coast, wood is lacking or very scarce and is used only for sled runners and for thin boat frames. At the southern extremes of their territory the Eskimos use driftwood for building their houses. In some areas where wood is lacking whale ribs are used as roof supports. Eskimo boats are of two kinds. The kayak is a one-man hunting boat, decked over except for the hunter's seat. The umiak, which is open and larger, is used for transportation and for whaling. The Eskimos of the Aleutian Islands and the Pacific coast area lived in villages, but elsewhere

they lived in scattered family groups. There were no tribal groups in the sense of a political organization but only in a geographical sense, indicating a group showing some cultural and linguistic uniformity.

Northern and Eastern Area.—The North American continent east of the Rocky Mountains and north of Mexico shows considerable environmental uniformity despite its great size and its wide range of latitude. Temperature range and precipitation are quite similar throughout the area. The whole eastern part is evenly covered with forest which to the west changes gradually to parkland and to the open grassland of the western plains. This environmental uniformity was reflected in a considerable degree of cultural uniformity. There were, of course, varying local adaptations, but during the pre-Caucasian period these did not reach any degree of intensification.

The prehistory of this area may, from present archaeological evidence, be seen as a sequence of four stages: Pre-pottery, Woodland, Hopewell, and Mississippian. Pre-pottery period sites are known from Massachusetts, New York State, the lower Ohio drainage, the Ozarks, the Mississippi delta, Florida, northern Texas and western Nebraska. These sites were also all pre-agricultural. The oldest of these sites are Clear Fork in Texas and Signal Butte in Nebraska. A date of 2000 B.C. is claimed for the latter. In any case, this eastern pre-pottery period extended back from the early centuries of the Christian era and may be as old as 3000 B.C. in some places. The Woodland period grew, largely, out of the pre-pottery period with the introduction of pottery-making and, perhaps somewhat later, maize agriculture. In some areas the Woodland culture persisted for a very long time while in other places local cultural developments grew out of it. Woodland pottery was cordmarked, a characteristic which can be traced northwestward to Asia and even resembles European Neolithic pottery. The implications of this resemblance are far from clear. The Woodland people also made smoking pipes, stone axes and chisels, and the so-called "banner stones" and "bird stones" of well-polished slate. Sites of this period are known from New England, Ohio, Illinois, Wisconsin, Kansas, Nebraska, and North Dakota.

Sites from the Hopewellian period are scattered along the Mississippi and its principal affluents, and also across the Gulf Coast to Florida. The highest accomplishments in eastern prehistoric art are from the Hopewell sites in southern Ohio. Particularly noteworthy are human and animal sculptures in stone, bone, and clay, elaborate curvilinear designs incised on pottery, large, finely chipped blades of obsidian and quartz crystal, and celts and elaborate ornaments of copper. It has been debated whether such Hopewellian traits as burial mounds, the accumulation of wealth, and the presence of chiefs were indications of importation or influence from Mexico. Because the greatest development occurred in Ohio, at the point farthest from Mexico, it seems likely that the Mexican influence was indirect.

The Mississippian period is known primarily from sites south of the Ohio River and east of the Mississippi plus some from Texas, Arkansas, and Oklahoma. Pottery from the later part of this period in Texas crossies with Pueblo pottery, giving a date of 1300-1450 A.D. During the Mississippian period mounds were built which

served as the bases for temples. Very fine work was done in modeled and engraved pottery, and with shells and copper. The question of Mexican influence arises again here. Mexican motives may be found, especially in material from the southern states. There was, however, clearly a development from the Hopewell period.

Turning to later cultural conditions in the Northern and Eastern Area, some regional variations appear. In the Northern area of coniferous forest reaching across the continent from Newfoundland to Alaska, farming was impossible and the wild game was thinly scattered. As a result, the population was also thinly scattered and cultural development meagre. The caribou, which ranged clear across this area, was the major source of food and also supplied material for clothing and tents. Other traits characteristic of the area are: spruce and birchbark canoes; toboggans; babiche and bark fiber; the use of snares and nets; cooking with hot stones in baskets made of split spruce root. The tribes of this area camped along the rivers traveling by canoe in summer and on the ice in winter. They were independent of each other, having no tribal political systems. There was also little religious activity except for the prominence of shamanism. Hudson's Bay constitutes a dividing line within this area. The tribes to the east of it are the Algonquian-speaking Saulteaux, Cree, Montagnais, and Naskapi, all of whom share the basic pattern of this area. To the west of Hudson's Bay were the Dene whose culture was similar to the more easterly groups with the addition of some influences from the Eskimo on the one hand (kayak, some fishing implements), and from the Northwest coast tribes on the other hand (social classes based on wealth, clans, the potlatch, use of armor). In this area there is also salmon fishing and some use of planks for houses as well as the tipi and lean-to.

The next subarea within the Northern and Eastern Area is the Eastern Woodland Area which consists of three principal groups: (1) the Iroquoian tribes (Huron, Wyandot, Erie, Susquehanna, and the Six Nations); (2) the central Algonquin, lying west of the Iroquois and including the Ojibway, Ottawa, Menomini, Sauk, and Fox, Potawatomi, Peoria, Illinois, Kickapoo, Miami, Shawnee, and the Siouan Winnebago; (3) the eastern Algonquin including the Abnaki, Micmac, New England tribes, and the Delaware. Because so many of these tribes became extinct early in historic times, the details of their culture are not too well known but the following traits are characteristic: cultivation of maize, squashes and beans; the use of wild rice and maple sugar where available; hunting of deer, bear and buffalo; fishing on the lakes; some pottery cooking vessels; also vessels of wood and bark; splint basketry; a winter bark or mat-covered lodge and a summer rectangular bark house; the use of canoes, toboggans and snowshoes; skin clothing for men and women. The two eastern divisions were more intensive agriculturalists and made more use of pottery. The Iroquois did superior work in bone and in carving wooden masks. They also had a highly developed political organization, typical of an eastern pattern of confederacies which reached its final development in late pre-white times. The best-known of these confederacies was the Iroquois League of the Six Nations, which included the Mohawk, Oneida, Onondaga, Cayuga, Seneca,

and Tuscarora. It seems certain that these large leagues developed out of a native pattern of small and unstable leagues. It also seems clear that the full development of these early leagues took place only after the pressure from white encroachment made a strong organization necessary and the acquisition of such Caucasian possessions as livestock and firearms produced a temporarily more stable economy.

The Southeastern subarea covers the region east from the Mississippi. It includes such tribes as the Natchez, Powhatan and Shawnee, all the Muskogean groups (e.g., Choctaw, Chickasaw, and Creek), the Eastern Siouan (Ofo and Biloxi), and the Cherokee.

This was an area of intensive agriculture. Maize, pumpkins, melons, and tobacco were raised before White contact and fruit trees were quickly taken over from the Europeans. Dogs were the only pre-European domestic source of food but chickens, hogs, horses and cattle were quickly adopted. Deer, bear, bison, turkeys and other small game were hunted wherever available. The houses in this area were usually covered with thatch or bark, and sometimes had plaster walls reinforced with wickerwork; towns were fortified with palisades; clothing was made of deer-skin, weaving was done with bark fiber and buffalo hair; fine mats were made of cane and some work was done with cornhusks; some special kinds of baskets such as the double basket and basket meal sieve were made; knives and darts were of cane; the blowgun was used; pottery was well made by the coil process with paddle decorations; there was no metal work or sculpture but some stone work. In some places temples, set on mounds, were used in sun worship; there were also elaborate rituals for planting and harvesting, and the political chiefs were considered to be under the sacred power of the Sun God. Strong confederacies were developed in this area, and there was a clan system and a society composed of chiefs and four classes of subjects.

The Plains subarea stretched from Texas to Saskatchewan and included the low plains or prairies on the east and the high plains along the foothills of the Rocky Mountains. It included such tribes as the Assiniboin, Arapaho, Blackfoot, Cheyenne, Comanche, Crow, Gros Ventre, Kiowa, Kiowa-Apache, Sarsi, and Teton-Dakota. The typical economy of the whole area was dependence on the buffalo and a limited use of roots and berries. There was a great development of work in skins, no basketry or pottery, and very little use of wood or stone. The typical dwelling was the conical skin tent or tipi. Social organization consisted of a simple band organization and a series of men's societies. The most important ceremonial observance was the Sun Dance but there were also minor ceremonial occasions. Within this general pattern were local variations. The tribes on the eastern border practiced agriculture, made some pottery and basketry, and performed agricultural ceremonies in place of the Sun Dance. They also had permanent houses covered with grass, bark or earth. The tribes on the western border depended more on deer and small game and less on the buffalo; they also made use of wild seeds and grains, and had brush and mat-covered shelters as well as tipis. They made good basketry but no pottery.

For the Plains area as a whole the period of florescence came with the introduction of the

horse by the Spaniards in the 17th century. Before that, the farming tribes along the eastern border and some tribes in the foothills of the Rockies penetrated into the Plains but permanent occupation was sparse. Once the use of the horse had been mastered, the Indians could move into the Plains and exploit the buffalo more effectively. Some tribes, the Teton-Dakota and Cheyenne, for example, are known to have given up farming and taken to the life which developed into what is thought of as typical Plains culture. The final development was an elaboration of the basic pattern. Plains life centered around the buffalo which was the chief source of food, material for clothing, shelter, tools and medicines. The use of the horse enabled the Indians to capture enough buffalo to support them. The typical social group of the Plains was the band, several of which constituted the tribe. The bands of a tribe assembled at the beginning of summer to perform the Sun Dance, which was a tribal ceremony thought to ensure good hunting and the general welfare. There followed one or more tribal buffalo hunts, after which the bands dispersed and passed the remainder of the year separately. Since inter-tribal warfare was waged mainly in summer, the gathering of the bands in this season was also a measure of defense.

THE CONQUEST AND AFTER

The story of the American Indians after the time of the conquest is, for the most part, one of sudden and violent change which contrasts strongly with the slow, gradual centuries of pre-conquest development. Meso-America and South America were the first victims of the conquest. The arrival of Cortes in the Aztec capitol, Tenochtitlan, in 1520 and of Pizarro in the Inca capital in 1532 initiated the same series of struggles which ultimately took place over most of the New World. The balance was, to say the least, uneven. Numerical superiority was the only advantage on the Indians' side, and this was greatly outweighed by the firearms, armor, horses and training of the Spanish soldiers. The people who reached the New World in the period of Conquest were the soldiers, priests, fortune-seekers and colonists from several different European nations. They came from Spain, Portugal, Holland, France and England for a variety of reasons: for the sake of conquest, immediate exploitation, religious conversion or settlement. The variety of their purposes on the one hand, and, on the other, the varying nature of the Indian groups encountered, meant that the effect of the arrival of the white men differed, somewhat, from one area to another. The results depended on such factors as density of native population, suitability of the area for the new types of land use, and the susceptibility of the natives to the diseases introduced by their conquerors.

In the Marginal and Tropical Forest areas of South America, the Indians living along the coast and the navigable interior waterways were quickly absorbed or exterminated. In the less accessible parts of these areas, the natives first experienced an indirect contact with Spanish culture. They received new crops, domesticated animals and some tools and weapons before having actual contact with the whites. Among some tribes this led to an improvement in their exploitive activities and an expansion of their native culture. With the added advantage of

the horse for hunting and packing, the tribes of the Pampas and Patagonia could exploit larger areas. Later, after their first direct contact, whether the white settlers were missionaries or colonists, the natives were gathered into settlements where their native culture was quickly lost and the natives themselves were exposed to decimating epidemics. In the Circum-Caribbean area, the Indians of the Antilles and of the coast and lowland areas were exterminated or absorbed very rapidly by disease and enslavement. In the less accessible regions, such as the mountains, the native culture survived, but with a loss of such distinctive characteristics as its class system, organized warfare and special craft production.

In the Andean area, also, the native population suffered a great initial loss. At the time of the conquest in 1532 the Inca Empire (Andean region from northern Ecuador to northern Argentina and northern Chile) contained about four and a half million Indians. By 1571 this number was reduced by more than half, and by 1796 there were less than a million Indians in the area. After the wars of independence in the 19th century, the Indian population again increased until, today, in the old Inca area of highland Ecuador, Peru, and Bolivia, there are five and a half million Quechua-speaking people, and in the Lake Titicaca area, 500,000 Aymara-speaking people.

The population of this Andean area is today one of the two instances of very high proportion of Indian individuals in the New World. Except for Paraguay and the remote tropical forest of the upper Amazon, the populations of the other South American countries are largely white and mestizo with some Negroes and mulattoes in Brazil. During the years after the conquest, the Indian population of the Andean area tended to concentrate in the highlands, leaving the coastal section for the Spanish and mestizo population. This is quite apparent today in the contrast between the colorful and vigorous highland people and the somewhat somber and pallid coastal population. The native Andean crops and system of agriculture continued in use. The Spaniards did introduce barley and wheat but these were never widely accepted. The Indian methods of terracing and irrigating persisted, and the use of the Spanish wooden plow and of oxen as draft animals were introduced. The chief Spanish contribution to subsistence was their domesticated animals, the pig, chicken, burro, horse, cattle, sheep, and goats. These were added to the native use of the llama and alpaca. The introduction of Catholicism was so swift that by 1650 the Andean area was officially considered to be Christianized. The native religion was wiped out and only a few simple rites and ceremonies survived. Along with the loss of native religion went a great change in native craftsmanship. Ceremonial objects, which had constituted a large part of their craft output, were no longer needed. The native techniques persisted in the making of some utilitarian objects. The old belt looms are used as well as the European treadle loom. Sheep's wool is used as much as llama wool. Metalwork has all but disappeared but wooden bowls and woven baskets and mats are still made. The pottery is coarser than the pre-conquest ware and poorly decorated. It is made, for the most part, by the old techniques although the potter's wheel is now also used. Indian houses are made in much the same way as before

but the large, public buildings were, of course, planned by Spanish architects. It is of interest to note in this connection that in the 1950 earthquake in the Cuzco area, the Spanish structures collapsed but the old Inca buildings survived. Most Indians of the Andean area continued to practice farming after the conquest, living in scattered, independent villages. Some are peon laborers on large haciendas, but many own their own land and live in communities which have many characteristics of native culture. In Peru and Bolivia there are 3,000 such communities of about 500 persons each. Every year, education and increased transportation facilities bring these rural areas into closer contact with the white, urban culture. Bilingualism is increasing, and gradually the native culture is being lost in the process of assimilation into the national culture.

In Meso-America the conquest began with the landing of Cortes and his soldiers at Vera Cruz in 1519. The Aztecs resisted bravely but in vain, and their emperor, Montezuma II, and thousands of their people were killed. Cortes then extended his conquest to Honduras and Guatemala. In Meso-America as in Peru a profound change resulting from the conquest was the imposition of the Spanish land-use pattern. This was a system of large estates worked by mass labor and was in complete contrast to the native system of communal lands allotted to individuals. Even in the case of such native empires as the Aztec and Maya (also the Inca in Peru), the trading and collecting of tribute which had brought widely scattered groups into contact had not done so at the expense of the local communities. In terms of items added to the native Meso-American culture, the Spanish introduced the burro, cultivation of wheat, sugar cane, coffee, potatoes and bananas. The use of money largely supplanted trade by barter. Iron tools, the plow and cart were added, and later the sewing machine, power corn grinder, and factory-woven cloth. In most communities pre-conquest deities and communal agricultural ceremonies were replaced by Catholic Church fiestas, and the cult of the saints replaced local and family deities. The native pattern in which religious and secular functions were combined has, of course, been replaced by one in which these functions are entirely separate.

The Indian population of Guatemala and Mexico has more than regained its aboriginal size. The estimated population for the two countries in 1500 is about three million people. In 1940 there were six million in Mexico and nearly two million in Guatemala. In proportion to the total populations of these two countries, 33 per cent of Mexico and 55 per cent of Guatemala is Indian. These figures are based on a definition of the word "Indian" in cultural rather than biological terms. That is, when natives have adopted the Spanish language, European clothing and other traits, they are no longer classified as Indians but as mestizos (mixed-bloods) even though they may be Indians racially. The proportion of individuals figured on the basis of Indian descent would be much higher than the proportions given. This classification of Indians on a cultural rather than racial basis reflects an attitude in which South and Meso-America differ from North America. In South and Meso-American countries a person is classed by his culture and not by his race. An Indian is a person with Indian culture; a Negro is a person

with African culture, a white has white culture although not necessarily a white skin. This results in great racial and social fluidity. A person who is born an Indian, may, by education, by occupation and by acquisition of white modes of dress, speech and living, actually become a white. Also, two men who are brothers may be classed differently, one as an Indian, the other as a white. The vast majority of Indians, as well as of Negroes, in these countries still have their native cultural background which limits their ability to compete in the national, white culture. Nevertheless, the social fluidity allows individuals of special ability to achieve any status within the national culture. Indians and Negroes alike have made significant contributions as artists, doctors, lawyers, writers, and legislators. Another result of this fluidity is the emergence in some South and Meso-American countries of local cultures which are a blend of Indian and white elements. The cultures of such groups as the Guarani of Paraguay, the Ladino of Guatemala and the Criollo of Argentina are blends and although part of the national culture also preserve distinctive Indian characteristics.

A further fundamental difference in the post-conquest patterns in South and Meso-America as contrasted with North America, is that North America became urban and industrialized, whereas South and Meso-America have remained essentially agrarian and have retained to a considerable extent the pattern of large landholders with masses of native laborers. The present situation of the Indians under these circumstances is difficult. Those who have no land live in communities on the haciendas; those who have a little land may attempt to cling to community life and native patterns; and those who have enough land are able to produce a cash crop but still retain the old, local patterns of life. Whatever the Indian's situation, and whichever adjustment he may attempt to work out, the transitional phases are characterized by economic and cultural instability requiring special consideration to help him achieve a constructive and permanent solution.

It is of interest to notice that the areas of present-day concentration of Indian population were pre-conquest areas of population density. Nine-tenths of all American Indians live in the highland countries of Meso-America and South America which were early centers of high cultural development and dense population. The Spanish cultures added some new items to the content of these native cultures, but there was not a great disparity in the wealth of culture content and much enrichment also flowed from Indian to Spanish culture. Because, in these areas, neither culture completely engulfed the other, a blend emerged which could not have occurred under circumstances of great cultural disparity.

North of Mexico the pattern of settlement differed from that in Spanish America. The colonists arrived, on the whole, in family groups, settled and worked as families. In the eastern United States and Canada they found an area of low population density. Some of the Indian tribes of the eastern United States experienced a temporary period of expansion when, by indirect contact with the whites, they received some new plants and animals. But when contact became direct, the natives' tribal economy and the villages on which their social life was based were destroyed and it was not long before the Indians themselves were virtually extinct. The

settlers wanted land and had little difficulty in conquering the Indians or pushing them westward until they reached the submarginal lands unsuited to white settlement.

It has been noted in an earlier section that the major development of the culture of the Plains Indians came as a result of their receiving the horse which had been brought to the New World by the Spaniards. This period lasted as long as the white man did not want the territory of the Plains Indians. After that came some of the bloodiest Indian wars and the establishment of the survivors on reservations. The tribes of the southwestern United States were in contact with Spanish civilization as early as the sixteenth century. Those tribes having a fairly advanced culture absorbed some Spanish elements and did not experience cultural disintegration. The Pueblo tribes of the Hopi mesas and of the Rio Grande Valley, and the Navajos and Apaches retained a large part of their aboriginal beliefs, practices, outlook and culture traits. Their ceremonial life is less influenced by missionary teachings and their social organization is less disrupted than is the case with any other New World groups. The Navajos have shown a remarkable increase in numbers. In less than a century they grew from 8,000 to 50,000; a higher rate of increase than that of the white population.

The characteristics of contact, conquest and reservation life are much the same for the Indians in Canada as in the United States. The exception is in the far north where a few partially assimilated tribes live. The largest group is the Eskimos who number about 36,000 (including those in Danish Greenland).

A dominant factor affecting Indians and Indian groups in North America has been the Anglo-American point of view about races and race segregation. This attitude, as we have already seen, was not held by Spanish and Portuguese people. In North America the races represented by the whites, Negroes and Indians have been, by tradition, socially segregated. Each of these groups contains within itself a wide range of occupational and social statuses and an Indian (or a Negro) may rise only within his own group. Because Indians have been physically separated on reservations their situation has been less obvious than that of the Negroes. It is, nevertheless, true that like the Negroes, they are classified on the basis of race and not, as in Spanish America, on a cultural basis.

It is estimated that in 1500, the Indian population of North America was about one million. Of these, about two hundred thirty thousand were in Canada and about seven hundred seventy thousand in the United States. The areas of greatest density were the Pueblo area of Arizona and New Mexico and a portion of central California. The only group which has made any marked increase is, as has been mentioned, the Navajos, who increased from 8,000 to 50,000 between the mid-19th and the mid-20th centuries. The general Indian population decreased. As of 1960, the Indian population of the United States was estimated at 524,000; that of Canada was an estimated 186,000.

The transformation of Indian life was not the only result of the meeting of European and Indian cultures. The white settlers were also influenced by the Indians and borrowed many useful things from them. This Indian influence

has contributed much to the distinctive flavor which sets contemporary New World cultures apart from their parent cultures in Europe. The American Indian added new items to the world inventory of plants and domesticated animals. Among about forty unique plants are food plants such as maize, beans, melons, squash, pumpkins, tomatoes, avocados, white potatoes, chocolate, chili peppers, pineapple, papaya, and manioc (the source of tapioca); and other plants such as rubber, tobacco, chicle, quinine, and coca (the source of cocaine). Among the domesticated animals unique to the New World are the turkey, guinea pig, llama, and alpaca. A few prepared foods are also Indian in origin: maple syrup, tamales and pemmican. Another group of items made by the American Indians and taken over from them includes: the hammock, toboggan, parka, moccasin, dog-sled, canoe, the various ways of smoking tobacco (the pipe, cigar and cigarette), and also the use of snuff. The Indian has contributed richness and color to the literature of North America and of Spanish America.

MALCOLM CARR COLLIER.

INDIANS, Education of the. Broadly speaking, the education of the American Indians has progressed through four major periods: pre-colonial, colonial, treaty, and posttreaty. For a proper understanding of its status in the 1950's, the subject should be reviewed in relation to the historical setting of each of the periods through which it has passed. Even then, however, the picture could be painted in only the broadest strokes. A more comprehensive treatise would require an analysis of the educational development of each of the approximately 300 Indian tribal groups, because attitudes toward education, opportunities for education, and educational

achievements vary as the historical conditions surrounding each group have varied. Furthermore, a definitive picture of Indian education in the 1950's would require the paying of some attention to the educational status of the many thousands of Americans who trace their origin immediately or remotely to Indian ancestors, but who have culturally lost their Indian identity.

Precolonial Period.—The ancestors of the American Indians occupied in precolonial times all of what is now the continental United States. The geography of the area in which each group lived largely determined its way of life, and the way of life of the group dictated in turn the educational needs of its youth. The youth of the Indian groups along the eastern seaboard were educated in the ways of the woods. They were taught to hunt and fish in the mountains and streams; to plant crops of squash, beans, and corn in the clearings; to protect themselves from the elements in winter and summer; and to perform the proper ceremonies in order to preserve and perfect their relations to a Higher Spirit. Young people growing up in Indian groups who roamed the prairies were taught the techniques of survival on the open plains—how to hunt the buffalo for food, and how to preserve and cure its hide for clothing and housing. Indians of the Northwest needed the skills of hunting and fishing and seed gathering, while the youth of the arid Southwest were taught how to conserve precious water supplies and to apply them to the raising of crops.

Education in precolonial days was related in a practical way to the needs of each group. Indian youth were informally, though carefully, taught, usually by their parents and grandparents, how to make a living, how to function in relation to other members of their group, and how to relate themselves to a Higher Spirit and to live morally according to the social values of their societies.

Colonial Period.—The white man, when he came to the North American continent, brought with him a pattern of life different in most respects from that of the Indian groups who were living in the areas where he settled. He imported his ideas of education, individual property ownership, religion, agriculture, medicine, and the accumulation of wealth, and conflicts of ideas developed rather quickly. Opposing conceptions of land ownership soon caused a struggle which resulted in some of the bloodiest encounters between the two races. History records the struggle for land from many points of view, but usually the Indian fought valiantly to protect his home and his family, and the white man from his point of view did the same.

The colonists attempted to Christianize and educate the Indian. The central purpose of education for the Indian, as the white man envisioned it, was to replace the Indian's way of life by eradicating completely his beliefs and customs and by substituting for them beliefs and customs of European origin. To achieve this objective, efforts were made to gather the Indians into towns and communities where schools and churches were established to teach non-Indian crafts, civic responsibilities related to township forms of government, and the Christian religion. The first such school was established in Cuba in 1568 by Jesuit missionaries for Florida Indians. John Eliot began in 1646 the development of Indian town communities in Massachusetts, and

by 1674 their number is reported to have increased to 14. Later, Franciscan missionaries in the West and Southwest encouraged Indians to settle around missions, where they were taught husbandry and Christianity. Harvard College by charter in 1650, the College of William and Mary in 1691, and Dartmouth College in 1769 were among the first colleges dedicated to Indian education. Through these and other efforts individual Indians assimilated to varying degrees non-Indian culture, but as a rule the Indians did not respond enthusiastically to the system of education offered. The reasons for the general nonacceptance of formal education could best be stated in the words of an Indian chief in reply to an offer to educate Indian youth:¹

We are convinced . . . that you mean to do us good by your proposal, and we thank you heartily. But you, who are wise, must know that different nations have different conceptions of things; and you will therefore not take it amiss if our ideas of this kind of education happen not to be the same with yours. We have had some experience of it. Several of our young people were formerly brought up at the colleges of the northern provinces; they were instructed in all your sciences; but, when they came back to us, they were bad runners, ignorant of every means of living in the woods . . . totally good for nothing. We are, however, . . . obliged by your kind offer, . . . and, to show our grateful sense of it, if the gentlemen of Virginia will send us a dozen of their sons, we will take great care of their education, instruct them in all we know, and make men of them.

Meanwhile, the impact of the conflict between Indian and non-Indian and the removal of the Indians farther and farther westward engendered a bitterness on both sides that retarded the education of the Indians for several generations.

Treaty Period.—As each group of Indians was conquered, usually, though not always, the conflict was concluded by a treaty between the federal government and the Indian group. In the treaty the government spelled out certain promises, such as tax-free land, and usually, though again not always, the establishment of schools for Indian youth. Regardless of the promises made in such treaties, however, Indian attitudes resulting from war experiences with non-Indians did not favor acceptance of the white man's schools. During this period missionaries made heroic efforts to rebuild Indian morale, but it was difficult for the Indians to reconcile the Christian principles enunciated by missionaries with their recent experiences with non-Indians.

The first formal recognition by the federal government of educational responsibility toward the Indians was an appropriation in 1819 of \$10,000, which was distributed to religious groups to further educational work among Indians. The federal policy of distributing annual appropriations to mission groups to carry on such work among the Indians continued until 1900, the amount appropriated each year increasing to \$611,570 by 1892. Between 1892 and 1900 there was considerable public discussion concerning the schools operated by the different religious societies, and federal policy was changed in the appropriation act for 1897, which declared it to be the policy of the government that no further appropriations be made in support of education in sectarian schools. Funds were appropriated for these schools through 1900, and thereafter the government established and expanded its own system of federally operated schools.

Under the sponsorship of the Branch of Education, Bureau of Indian Affairs, special students are given courses in driver education.

The central purpose of education during the treaty period was to Christianize and remake the Indian in conformity with non-Indian patterns of living. Most educators of the time came to believe that the fastest and surest way to achieve this transformation was through boarding school education, which would separate Indian children from their families and surround them with a non-Indian environment. Consequently, great emphasis was placed on boarding schools.

Posttreaty Period.—By the close of the 19th century federal support of sectarian education had been replaced completely by a federally operated system of schools, which was being expanded rapidly through the conversion of abandoned army forts to school use and through the construction of new schools. One example of an army post converted to school use was Carlisle Indian School, which was founded by Capt. (later Gen.) Richard Henry Pratt in 1879 at Carlisle, Pa., and made famous by its athletes. Such celebrated figures as James Francis (Jim) Thorpe and Glenn L. (Pop) Warner publicized the athletic prowess of the student body. In addition, Carlisle became known for its outing system of placing students in Pennsylvania homes, where they lived as members of the family and learned the American way of life. Carlisle was closed as a school in 1918, but in the 1950's many of the older generation of Indians still could recount vividly their experiences at that institution.

During this period several new school plants were built, among them Chillico Agricultural School, in Chillico, Okla.; Haskell Institute, in Lawrence, Kans.; Phoenix Indian School, in Phoenix, Ariz.; Albuquerque Indian School, in Albuquerque, N.Mex.; Hayward Boarding School, in Hayward, Wis. (now closed); and Pipestone Indian School, in Pipestone, Minn. (also closed). In addition, a few day schools were established. Emphasis was placed on boarding school education, however, primarily in the belief, which continued to persist, that the most effective way to educate Indians was to remove children from an Indian environment and to surround them with a non-Indian way of life. Con-

sequently, boarding schools were established away from the homes of Indians, usually near some urban center.

Indians did not respond willingly to this method of education. By various means they were induced or compelled to send their children to school, but usually the Indian family selected one child who attended school as a duty to be met in the name of the family. Emphasis was placed on instruction in English, husbandry, and domestic arts. Some of the boarding school students of the period never returned to their homes. A number who did return to their reservations became confused by the conflict between the two ways of life, while others were soon submerged once more in Indian life, although many later emerged as tribal leaders after attaining the maturity required for Indian leadership. Judged in the light of mid-20th century educational methods and standards of instruction, the harsh methods of punishment of the period, especially punishment for speaking native languages, and the strict military discipline and atmosphere that typified the school administration must be condemned.

An act of Congress of 1924, commonly known as the Citizenship Act, marked a major turning point in Indian affairs and had an extremely important relationship to Indian education. This act, which conferred citizenship on all Indians within the continental United States, gave them the right equally with other citizens to look to state and local governments for educational services. This posed serious problems for the states, primarily in two respects: (1) The nontaxable status of Indian lands resulted in the inability of many local public school districts to assume financial responsibility for the education of Indians. (2) Much Indian land had never been included in school districts.

Although the federal government realizes that education is a state responsibility, it recognizes that states and local districts must have an adequate financial base in order to operate schools. In districts deprived of sufficient financial resources to operate their schools because of the presence of nontaxable Indian land and of large numbers of Indian children to be educated, the Bureau of Indian Affairs therefore makes a financial contribution under the authority of the

INDIANS, EDUCATION OF THE

Johnson-O'Malley Act of April 16, 1934, as amended, in order to permit the schools to operate under adequate standards. Public Law 815 of Sept. 23, 1950, as amended, which is administered by the Office of Education, Department of Health, Education, and Welfare, has speeded the process of placing Indians on the same educational footing as other citizens by providing financial assistance for school construction in Indian areas. In the fiscal year 1957 the Bureau of Indian Affairs provided assistance to needy school districts through contracts in 19 states and the Territory of Alaska.

During the Hoover administration, Hubert Work, then secretary of the interior, engaged the Institute for Government Research of Washington, D.C., to make a searching study of Indian administration, including Indian education. As a result of this investigation, the findings of which were published in 1928, Indian educational policy was radically changed, and the approach was reversed from one of removing Indians from their homes to one of educating Indians within their home environment. This permitted the school to become an important agent of change, its learning leavening and advancing the entire group, adults as well as children. The newer approach of education probably did more than any other single factor to reverse the negative attitude of Indian parents toward formal schooling for their children. The newer policy was reinforced by congressional action outlined in the Indian Reorganization Act of 1934. Consequently, many boarding schools were closed, and day schools were established to replace them. The new day schools became community-centered institutions emphasizing the education of both children and adults. Their programs were developed around the needs of the group they served, which included health, sanitation, community and home improvement, stock improvement, recreation, and the like. Through these community schools, Indians acquired new ideas, which led to fresh ambitions and improved living standards. These schools began to dissolve the psychological boundaries that set Indians apart and to motivate them to seek opportunities beyond the reservation boundaries.

Willard Spotted Horse, a 20-year-old Crow Indian, learns the welder's trade at Haskell Institute, Lawrence, Kansas.

Because of geographical factors of isolation, however, it was impossible to eliminate all boarding schools. In many areas, Indian populations were so scattered that such schools were the only means of providing education. When no other educational plan was feasible, boarding schools on reservations were retained, but their curriculums were revised to conform to the new educational policies.

Educational Programs.—Thousands of American Indians have lost their cultural identity as Indians, and function fully as citizens on the same basis as non-Indians in their respective communities. Of the 142,000 Indian children of school age whose parents still retained in 1957 some degree of relationship to the federal government because of federal trusteeship over Indian land, 60.7 per cent were in public schools, 30.5 per cent in federal schools, and 8.8 per cent in mission and other schools. Of those attending federal schools, 82.6 per cent came from fullblood families in which the Indian language was usually that spoken in the home.

In 1957 the Bureau of Indian Affairs operated 95 boarding schools of all types and 229 day schools; of these, 26 were operated as fully accredited high schools. In addition to the fundamentals ordinarily taught, the curriculum of the

federal schools gives special attention to instruction in communication skills, vocational and homemaking skills, and the social skills important in successful adjustment to modern living.

Higher Education.—The Bureau of Indian Affairs encourages Indians to pursue post-high school courses, both college and trade, and provides assistance through limited federal grants and federal loans. It also encourages Indian groups with the financial resources to do so to establish scholarship programs. In 1957, 23 tribal groups were operating scholarship grant programs and 67 were making loans for education and other purposes. The Jicarilla Apache and the Navajo tribes have set aside \$1,000,000 and \$5,000,000, respectively, and use the income from these funds to provide grants for the higher education of their youth. In addition, some states provide scholarships for Indian residents.

This accelerated emphasis on financial aid for higher education has led to the enrollment of greater numbers of Indians in colleges and universities. In 1957 approximately 2,800 young Indians were in schools of higher learning and many of these were receiving financial assistance from various scholarship programs.

Adult Education.—The Bureau of Indian Affairs initiated in 1956 a pilot program of adult education for Indians who had failed to obtain formal education in their youth. Geared to the literacy needs of these groups, this program aims to impart a workable knowledge of English and to develop the fundamental skills and understandings necessary for living in a modern world. Emphasis is placed on the development of basic understandings in the management of money, time, and family responsibilities required

Navaho and Alaskan Education.—The largest remaining federal operation in the 1950's was concerned with Indians in the Southwest and in Alaska. Recency of educational opportunities for these groups made continued federal operation necessary.

Although as late as 1946 only one Navaho (Navajo) child in four had an opportunity to attend school, a combination of factors—the location of a few day schools among the people, the impact of World War II, and a diminishing resource base—resulted in a radically changed point of view on the part of the Navaho Indians during the succeeding decade. In 1953 the federal government declared the out-of-school situation on the Navajo Indian Reservation an emergency and instituted emergency measures to place all Navaho children in school. Temporary facilities and trailer schools were located on the reservation, existing reservation schools were expanded, and facilities were developed in public schools nearby. This all-out effort reduced the out-of-school Navaho population of school age from 13,000 in 1954 to approximately 3,000 in 1957.

Schools for the native children of Alaska—Eskimos, Indians, Aleuts—are operated under two systems, a territorial system and a federally operated system. Federally operated schools were established in 1884 by the Office of Education and in 1931 were transferred to the Bureau of Indian Affairs. As of 1957, 11,426 Alaskan native children were enrolled as follows: federal schools, 4,558; territorial schools, 6,144; mission schools, 724. A total of 84 federal schools were operated, 2 of them as boarding schools and the remainder as day schools in native villages. Native children attend one federal high school and several territorial high schools. The best estimates indicated that there were approximately 1,200 pupils in Alaska without facilities in 1957.

Organization.—Indian educational policy is developed by the commissioner of Indian affairs and his staff, technical assistance being provided by trained educators. The program of education is administered through a decentralized system of 10 area offices, each headed by a director responsible for the administration of all programs within his area, including education. Area directors delegate responsibility for the operation of schools to local school administrators, who administer local education programs in accordance with policies established at national and area levels. Federal schools are supported by annual appropriations made by Congress.

Approximately 90 per cent of the nonprofessional and semiprofessional jobs involved in the operation of the schools are filled by Indians, more than 50 per cent of the professional teaching positions are occupied by qualified Indians, and between 25 and 33 per cent of the key administrative and supervisory jobs in the field of education are held by Indians. Teaching positions in the bureau are secured through competitive civil service examinations. Qualifications include a college degree with specific training in education methods. In 1956 salaries for these positions ranged from an entrance salary of \$3,670 a year to a maximum of \$5,335. Promotions to higher-paying administrative and supervisory jobs are usually made from within the service to employees who have demonstrated their ability and meet the requirements of the specific job. Salaries for administrative and supervisory jobs range from \$5,440 to \$11,395.

Indian girls learn the art of cookery in the cafeteria kitchen at Ganado Mission High School, Ganado, Arizona.

by modern society. This instruction gives meaning to a systematically developed English vocabulary taught in relation to the newer ideas.

In addition, vocational education opportunities are provided for adults who wish to take jobs in industrial centers but lack the basic skills for such employment. Industrial educational opportunities are secured in trade schools. After the completion of a course of study, Indian adults are placed in newer types of jobs where they can utilize their new skills and so enjoy a higher standard of living.

INDIC LANGUAGES, the name given to the languages of the Indian branch of the Indo-Iranian subfamily of the Indo-European languages. Among the most important are Hindi, Bengali, and Panjabi. See also INDIA—9. *Languages*; INDO-EUROPEAN LANGUAGES; LANGUAGES OF THE WORLD—*Linguistic Families*.

INDICAN, in'dī-kān, a natural crystalline glucoside present in varieties of the indigo plant, and having the formula $C_{16}H_{17}NO_6 \cdot 3H_2O$. It is readily hydrolyzed to indoxyl, C_8H_7ON , and dextrose, $C_6H_{12}O_6$. Plants containing indican have been a source of the blue dye, indigo (q.v.), since the days of the ancients. They were cultivated in semitropical countries until the development of a successful process for the manufacture of indigo in the latter part of the 19th century.

Indoxyl is readily oxidized in alkaline solution to indigo. It is synthesized by a reaction between aniline and monochloroacetic acid, the resulting phenylglycine being converted by soda-amide and caustic soda to the final product.

INDICATOR. See CHEMICAL ANALYSIS—*Quantitative Inorganic Analysis*.

INDICTION, a period or cycle of 15 years, believed to have been adopted from Egypt by Rome in the 4th century A.D. as a basis for making property assessments. In the time of Athanasius (293?–373) it came into favor among ecclesiastical writers, and in the Middle Ages it was widely used in Europe. The Constantinian system reckoned indictions from Sept. 1, 312, while the imperial (also known as the Caesarean or Western) system began on Sept. 24, 312. The pontifical (also known as the papal or Roman) system adopted by the popes in the 9th century was based on the beginning date of Jan. 1, 313, and after the 12th century was based on the birth of Christ.

The indiction may be found by subtracting 312 from any year A.D. and dividing the result by 15, or by using the birth of Christ as the beginning date, adding 3 to the year, and dividing the result by 15, the quotient indicating the indiction and the remainder the specific year of that indiction. Thus, by these methods, the year 1957 corresponds to the tenth year of either the 109th or the 130th pontifical indiction, depending on the beginning date used.

INDICTMENT, in law, one of several methods that provide a defendant with a formal, written accusation specifying the crime with which he is charged. An indictment is found by a grand jury from the evidence presented to it by a district attorney or a similar prosecuting official, and is returned by the jury to the court which impaneled it. The term "bill" is applied to an indictment before the grand jury finds it to be a "true bill." It then comes into being as an indictment to serve as the basis of the prosecution of the crime charged therein, against the

person identified there, by name or by such a description as John Doe or Jane Roe.

Indictments are of ancient origin in English law, having evolved from the presentment. Like indictments, presentments are found by a grand jury, but from evidence of its own knowledge or by the jurors on their own initiative rather than at the instigation of prosecuting officials. Like trial by jury, these two forms of accusation constitute one of the bulwarks, of which Anglo-Saxon law is so justly proud, against unlawful accusations and convictions.

The United States Constitution provides in its Bill of Rights that "No person shall be held to answer for a capital, or otherwise infamous crime, unless on a presentment or indictment of a Grand Jury . . ." (5th Amendment), and that "In all criminal prosecutions, the accused shall enjoy the right . . . to be informed of the nature and cause of the accusation . . ." (6th Amendment). These provisions are echoed in the constitutions of the states. Since the Constitution requires only infamous crimes to be presented by indictment or presentment, lesser crimes are frequently presented by an information (q.v.), an essentially similar procedure initiated by the public prosecutor without any grand jury proceedings.

Still other methods of charging the commission of a crime exist. Some states have accusations in forms prescribed by statute. In addition, there are complaints and affidavits preferred by private individuals; these are often restricted to such violations as those against municipal ordinances of the nature of zoning. There are also a few forms no longer in use, such as those initiated by a coroner's inquisition or a jury verdict in a civil case. Although these still exist, they cannot per se serve as accusations, but they may be the basis for the issuance of an information by a state's attorney or of a presentment by a grand jury.

The statutes of the various states exhibit great diversity concerning the crimes which must be prosecuted by indictment and those for which an indictment, a presentment, or an information will lie. In general, the distinction that such lesser crimes as misdemeanors may be based on an information will hold. Many states will allow any crime to be charged by an indictment, however, and custom and efficiency then decide when an information will be used. There is a similarly great variety as to which crimes are designated as infamous, the general rule being that these constitute felonies and crimes punishable by at least one year's imprisonment in a state institution.

To be valid an indictment must give specific information and must be drawn with strict regard for technicalities. Although the law has become less strict, and although immaterial errors may be corrected on trial, major inaccuracies will void an entire proceeding, and a trial and any conviction thereon will be a complete nullity. Furthermore, many states will not allow a waiver of the completeness of the indictment, and its imperfections may be attacked at any time.

Indictments are found solely on the evidence presented, which must constitute a prima facie case, showing by the testimony of witnesses or by the use of documents all the essential elements of the crime. Naturally, the grand jury is presented with only such evidence as is pre-

sumed will be available and admissible during the trial. Only the main points of evidence are presented, however, and without the details or procedure necessary in a trial most indictments can be found a true bill or refused in a few minutes. An indictment is prepared by a district attorney, usually even before the case is presented. If it is found valid, it is signed by the foreman of the grand jury and filed with the court, and a summons or warrant is then issued. The deliberations of a grand jury are held in secret, and its records can be made public only through a court order. The accused does not appear before the grand jury to object, since he is presumed innocent until the indictment is brought to a court trial, where he can prove his innocence or show the impossibility of proving the truth of the charges. In these matters the laws of the states are substantially similar, and the Federal Rules of Criminal Procedure have been deliberately framed to approximate closely the practice general to most states in this regard.

INDIGESTION. See DYSPEPSIA.

INDIGIRKA, ĭn-dĭ-gĭr'kă, river, USSR, located in the RSFSR, in eastern Siberia, in the Yakut Autonomous Soviet Socialist Republic. It rises on the northern slopes of the Verkhoyansk Range and flows in a generally northerly direction for 1,113 miles, crossing the Cherski Range and passing through a frozen tundra to empty into the East Siberian Sea at 71° north latitude and 150° east longitude. There are few villages along its banks, and the river is navigable for more than half its length for 10 to 12 weeks from June to September.

INDIGO, ĭn'dĭ-gō, the common name of a genus of plants and of the blue coloring matter obtained from them. The indigo plants are tall herbs of the pea family, forming the genus *Indigofera*, of which there are several color-yielding species in various warm parts of the world. The one yielding most of the commercial product, and formerly extensively cultivated, is *I. tinctoria*, which is native to India, grows to a height of four to six feet, and has pinnate leaves. A West Indian species, *I. anil*, also yields indigo.

Indigo plant (*Indigofera tinctoria*).

The wild indigo of the United States is any of several species of a closely related genus, *Baptisia*, which flourishes especially in the Southern and Eastern states. Of these the best known is the yellow-flowered *B. tinctoria*, or indigo broom, which has been used as the source of a blue dye and to some extent as a medicine.

Until the opening of the sea route to India in the 15th century the only blue vegetable dye available in Europe was that derived from *Isatis tinctoria* or woad (q.v.), which was limited and costly. Indigo was therefore regarded as one of the most valuable of the new commodities from the Orient, and large funds were soon invested in its cultivation in India, Ceylon, China, and other places, where a profitable industry continued until after the middle of the 19th century. The best quality of indigo was obtained from eastern India, but indigo plantations were started also, with more or less success, in Brazil, Central America, and Mexico. Experimental plantations of early settlers in the United States, from Maryland to Louisiana, failed to survive for long after the American Revolution, mainly because tobacco, cotton, and food crops were more profitable. With the discovery of cheap methods of forming blue dyes from coal tar the cultivation of indigo declined greatly, but it still supplies a small demand from dyers who wish an imperishable blue of certain hues.

The coloring matter of indigo is obtained principally from the leaves, especially at the time of flowering, when the crop is gathered by cutting down the plant and either making immediate use of the green stems or foliage or drying them for later treatment. This coloring matter is a chemical substance called indican (q.v.), the glucoside of indoxyl, which is converted by oxidation into indigo. The leaves and stems are macerated in vats for several hours. Fermentation begins, and the water becomes a clear yellow. The water is then run off into a lower basin, where it is subjected to incessant agitation and gradually turns green, whereupon the indigo begins to form in flakes and to settle. The residuum is thoroughly boiled, filtered through linen, molded into small cakes, and dried.

Before it can be used in dyeing indigo must be brought into solution; and, since indigo itself is insoluble, it must first be transformed into a soluble substance so that it can penetrate the pores of the cloth, where it is subsequently restored again to the form of indigo. To bring the indigo into solution it is ground to a soft paste with water, after which it is thrown into vats with ferrous sulphate, slaked lime, and water. The ferrous sulphate reacts with the lime to form calcium sulphate and ferrous oxide, the latter being immediately oxidized at the expense of part of the oxygen of the indigo, which in its turn is reduced to a substance called indigo white. This dissolves in the presence of excess of lime, and the fabric to be dyed is dipped into the vat after the liquid in it is clear. On removing the fabric, the indigo white which has penetrated its pores is reoxidized by the air to indigo blue, and by repeating this treatment a shade of blue of any desired depth may be obtained. The dyed fabric is finally passed through dilute acid to remove any adhering lime or ferric oxide.

Indigo is now made artificially, production of synthetic indigo having shown a marked increase, along with other types of synthetic dyes, since

World War II. Artificial indigo blue (also known as indigotin) has the chemical formula $C_{16}H_{10}N_2O_2$ and appears to be identical with the natural product in every respect. Although used primarily for dyeing fabrics, indigo is used in the manufacture of certain printing inks and other products. See also DYES AND DYEING.

INDIGO BIRD, a numerous and beautiful North American finch (*Passerina cyanea*), the male of which is dark greenish blue, while the female is grayish brown. They are migratory, but in summer spread over most of the United States, placing their neat nest and unspotted bluish eggs in garden bushes as well as in wild thickets. The male has one of the brightest and most persistent songs of any American bird, and he is easily habituated to captivity.

INDIGO SNAKE. See GOPHER SNAKE.

INDIRECT DAMAGES, claims for damages not directly inflicted by the illegal act complained of, but by other causes themselves due to that act. The great historical case is that of the United States claim for many hundreds of millions of dollars' worth of loss, resulting from Great Britain's bad faith or carelessness in letting the *Alabama*, the Confederate cruiser, escape from her ports to prey on our commerce. It was alleged that aside from the actual loss to our shipping and cargoes, we had been damaged to a far greater extent by the resultant effects, chiefly of three sorts: (1) The prolongation of the Civil War due to the encouragement given to the South and the straitening of the North. (2) The destruction of commercial lines and relations, which took long to recover after the war. (3) The raising of the rates of marine insurance. As these claims exceeded the cost of a war plus the indemnity we should have exacted if victorious, Great Britain refused to consider them; and the commission threw them out altogether as contrary to international law.

INDIUM, a shiny, ductile metallic element of a silver-white color, discovered by Ferdinand Reich and Theodor Richter through spectroscopic analysis during 1863 in the Freiberg arsenical ores. It is very rare. It is related to cadmium and zinc, and both are associated with it in nature; but it is found in many ores besides, although especially in zinc blende. This metal is obtained by heating the oxide with carbon and by other methods. It is soft, malleable and easily fusible. Its distinguishing property, however, and the characteristic which led to its discovery, is the indigo-blue line which all its compounds—so far as investigated—show in the spectroscope. The spectrum of indium exhibits two characteristic lines: one violet line α , and another blue line β ; and besides these two fainter blue lines are visible if the burner in which the metal is volatilized be fed with hydrogen instead of coal gas. Its specific gravity is 7.1–7.4; its symbol In; and its atomic

weight 114.8. It melts at 155°C . ($=311^{\circ}\text{F}$.) and vaporizes above $1,450^{\circ}\text{C}$. Chemically, indium resembles aluminum and gallium, being chiefly trivalent. See also ATOM—Shell Structure of Atoms; CHEMISTRY; METALS; PERIODIC LAW.

INDIVIDUAL DIFFERENCES, Psychology of. In any science the primary interest is in the typical phenomena and general laws of the field. So it has been in psychology; but the interest of some investigators in subjecting the very differences between people to scientific treatment as phenomena in their own account has been powerfully supported by the modern interest in testing and classifying individual persons. Differential psychology, as it is also called, has come into its own with the demands of application in many practical areas.

Basic to all work in this field is the statistical concept of the normal curve of chance distribution (see Fig. 1, which is plotted from the expansion of the algebraic binomial $(x + y)^n$). It has been observed by other scientists and mathematicians that the laws of chance which govern the fall of a coin or a die obtain also for the occurrence of anatomical traits such as height or chest girth, and, as the psychologist Francis Galton found (see *Bibliography*), for the occurrence of mental traits of a great many kinds. Mathematically, the composite effect of innumerable factors operating independently upon a trait is to produce many occurrences of medium amounts of the trait with fewer and fewer cases of extremely high or extremely low amount, the gradation being represented not by a straight line but by a bell-shaped curve. Methodologically, then, we may expect to find most mental characteristics appearing in a great number of individuals in the proportions suggested by the curve; and clear departures from the curve then suggest the operation of some factor or factors that call for identification. The statistical and graphic methods with elaborations are useful in bringing out many aspects of individual differences: how a given John Doe resembles or differs from his group; how one group of people compares with another in their average score; how one group may have more scattered scores than another; how two mental abilities may or may not vary together.

Turning now from methodology to content and findings, we may limit our survey to two problems. *Male and female* differ, of course, anatomically especially after puberty. So far as intelligence is measurable, no reliable difference at all is found. Great differences in emotionality between man and woman are popularly assumed, but they have not been demonstrated experimentally—though available methods of measuring are far from adequate. In types of interests very great divergence is the rule, but here we deal with something that is certainly a product of social pressures and encouragements and hardly at all a matter of fundamental sex difference.

There is no basis for sorting human beings that is more commonly employed and more provocative of violence than that of *race*. Investigations of racial differences are peculiarly subject to errors that creep in from many sources aside from the unconscious biases of the examiners. For instance, to measure different races of people on American soil, or to apply to Polynesians or Mongolians tests that have been standardized in American schools, is to overlook serious conditions that may blanket out true

Fig. 1. Frequency curve with standard deviation as a unit of measure on the base line. The mean score of the distribution is 100 points, the standard deviation is 30 points. Note the area of the curve (that is, the number of individual cases) comprehended by 1, 2, and 3 S.D.'s respectively, taken above and below the mean.

differences or may produce specious ones. Franz Boas' statement made in 1894 is as valid today: "The average faculty of the white race is found to the same degree in a large proportion of individuals of all other races." In this area as well as in other dimensions of variation, the sound rule is: so far as native traits are in question, what counts is not the group to which a person happens to belong; it is himself.

Some general conclusions that are much emphasized may be noted. The differences between individuals from the same group often exceed the differences between the means of different groups. Generally abilities go together, so that the individual who stands high in his population in one ability is somewhat more likely than not to stand high in another ability—popular opinion to the contrary notwithstanding. The effects of culture (that is, rearing, education, and social environment generally) are unquestionably very great in producing differences easily confused with native differences.

JOHN FREDERICK DASHIELL,
Kenan Professor of Psychology, University of
North Carolina.

INDIVIDUAL LIBERTY, in political theory, freedom from external restraint in the exercise of rights that in a nation organized under a constitutional government are regarded as lying outside the area of government control. Individual liberty is distinguished from *civil liberty*, which is a citizen's *natural liberty* restrained by law only as far as required by essential public interests, and from *political liberty*, the freedom of citizens to participate effectively in government.

Individual liberty includes *personal liberty* (freedom to come and go without hindrance), freedom of opinion and its expression, freedom of conscience and worship, equality before the courts, and security of private property.

INDIVIDUAL PSYCHOLOGY is both a theory of personality and a method of psychotherapy. First formulated and developed by the Austrian physician and psychologist Alfred Adler

(1870–1937), it has come to be of international importance as a system for the understanding of personality and for the prevention and treatment of a wide range of personality ailments.

Individual psychology is one of several "schools" that, in part at least, grew out of Sigmund Freud's psychoanalysis. From 1902 to 1911 Adler was a member of the circle of personal associates of Freud in Vienna, and it is therefore not surprising that individual psychology and psychoanalysis are alike in some respects, for example in their emphasis on unconscious motivation and on childhood experiences and in their belief in the psychogenesis of a wide range of disorders of personality. In 1911, however, Adler left Freud's circle and established his own "school," for by this time important differences between their points of view were becoming increasingly apparent. These differences included Adler's emphasis on the striving for superiority rather than the sex drive, his insistence that neuroses result from disturbances in interhuman relationships rather than from conflicts in the unconscious mind, and his contention that the task of the psychotherapist is to interpret any given symptom in the light of the patient's life goal and his total personality structure rather than to explain the symptom in terms of cause and effect. Adler called his system "individual psychology" because he wanted it to be a personalized approach to personality that studies each individual as a unique whole, with special emphasis on the meaning that interpersonal relations have for him. At the same time he was fully aware that his system, like that of Freud, had many social implications of a far-reaching character.

Principle of Compensation.—As a physician, Adler was naturally interested in the organs of the body, and these, in a sense, were the starting point of his thought. He went on from them to point out that the principle of compensation which plays such a large role in their functioning is also found in the activities of the human psyche. Just as the loss of one kidney results in a compensatory growth of the remaining kidney, with no conscious effort on the part of the individual concerned, so does the psyche tend to compensate for felt organic defects when the organ's natural resources are unable to compensate for its functional weakness. Compensation, a phenomenon of all living things, is as valid a process in mental life as in the realm of the biophysical.

Striving for Superiority.—Individual psychology is dynamic in that it emphasizes the role of motivation in human life, and compensation is the principle that is involved in the production of the great motive called the striving for superiority or the will to power. Every human being has felt inferior as a weak and helpless child in an adult world, and from this "primary" or "relative" feeling of inferiority has come a compensatory striving for superiority.

This feeling and this striving are in no sense abnormal. Because of the operation of any one or more of a number of factors, this "relative" feeling of inferiority can turn into an "absolute" feeling of inferiority that leads to either a neurosis (involving a "Yes, but" attitude toward life's responsibilities) or a psychopathic condition (involving a "No" response). Three predisposing factors commonly found are (1) bodily defects, (2) a pampered childhood, and (3) a neglected childhood. Whether such factors produce un-

desirable personality effects depends upon the individual's reaction to them.

It is not surprising that bodily defects should be regarded as a type of predisposing factor in changing the "primary" or "relative" feeling of inferiority into an "absolute" one. People frequently, though not necessarily, react to a bodily handicap by developing a defeatist attitude. The effects of childhood pampering and childhood neglect are not quite so obvious. Pampering creates an unreal world for the growing child, and sooner or later the individual so reared will experience a great shock when he attempts to make the transition to the real world outside his home. The exalted position that he enjoyed as a child will not be his as an inherent right in the outside world, and he will feel that his status is below what it should be. As for the neglected child, he tends to develop the feeling that he is missing something and that his status is inferior to that of other children who receive the care and attention of loving parents. He is likely to regard the world as an unfriendly place in which he must fight in order to survive, an attitude that predisposes him in the direction of antisocial and criminal behavior.

Whatever the real or imaginary factors to which the individual reacts in such a way as to develop an "absolute" feeling of inferiority, an important result is an intensification of his striving for superiority. In general, the more inferior an individual feels the more he yearns for superiority, and the strength of his drive for superiority is a measure of the depth of his feeling of inferiority.

Individual psychology's teaching that the striving for superiority is a fundamental human motive has frequently been misunderstood to mean that the desire for superiority over other people is a basic motive found in all human beings. The fact is that Adler regarded the desire for superiority over others as either a neurotic or a psychopathic tendency. He was, however, in part responsible for the misunderstanding, for he used Friedrich Nietzsche's phrase "the will to power" as a way of characterizing the striving for superiority, without clearly showing wherein his meaning of the phrase was different from that of Nietzsche. "The will to power" in Nietzsche's sense is an instinct in human nature that is the source of nobility in human life, and nobility is conceived in egoistic and aristocratic terms, with some individuals inherently greater than others. Nietzsche's "will to power" was thus for Adler a symptom of neuroticism or of a psychopathic condition. Adler's "will to power" is a normal and universal human motive for the individual to compensate for and thereby to overcome felt defects, to be superior not to his fellow men but to his own weaknesses.

Life Goal and Style of Life.—In contrast to the mechanistic approach of some schools of psychology, individual psychology is emphatically purposive, holding that no personality can be adequately understood merely in terms of causal determination in the same sense in which the physical sciences explain their phenomena in causal terms. To understand a human being involves more than an explanation in the cause and effect sense; there must also be interpretation of behavior in the light of the individual's personality structure as a whole and especially his specific purposes and his life goal.

The life goal is a generalized purpose or ob-

jective, the thing the individual fundamentally wants. It is set up unconsciously in childhood, usually by the age of four or five. Here the attitudes of the parents, the child's position in the family, and the atmosphere of the home are of great and enduring importance, for the life goal formed at this early age tends to be permanent. The child must be helped to know and to feel that he is an integral part of the human family, that he has something he can share with others, and that in so doing he can experience genuine satisfactions.

Life goals are of two basic types: those that are useful in promoting human welfare and those that are useless or antisocial. If the individual is to live in full accord with his own inner nature, he must have as his goal the making of his best contribution to mankind. There is something in man that favors a life of contribution.

Adler even expressed this way of looking at things in a cosmic setting, holding that there is something in the universe that favors those who give their best to humanity. In contribution is to be found the meaning of life.

A companion concept of the life goal is that of the style of life. The individual's style of life is his characteristic manner of meeting life's problems, the typical "how" of his adjustments. Living is a fine art, and, like any artistic performance, it involves a technique that is unique with each performer. The manner in which a human being relates himself to life is a distinctively personal matter, like the musical style of Bach or Debussy.

The key to the understanding of an individual as a unique whole is to be found in the study of his life goal and style of life. The individual psychologist does not ask himself, "What is the cause of this trait or this symptom in this person?" The question that he tries to answer is rather, "What is the goal of this total personality, and how is he seeking to attain it?" After the latter question has been answered he will understand the meaning of the trait or symptom, its importance and value to the individual, and its relations to other traits or symptoms.

An individual's life goal and style of life are shown in the way he attempts to solve his problems, especially the three great problems of social adjustment, sex adjustment, and vocational adjustment. Of these three the most significant is the problem of social adjustment, for it is the first major problem the child faces as he develops, and the way he solves it sets the pattern that he is likely to follow when he faces the other major problems.

Psychotherapy.—The need for psychotherapy grows out of the fact that many people have a life goal that is useless or antisocial. Large numbers of human beings are trying to get from life more than they are willing to give to life. Socially considered, the objective of psychotherapy is to promote the general welfare by helping these people to see that they have made a serious mistake in their life orientation and to take effective steps to correct it. This is a task of staggering proportions.

Individually considered, the objective of psychotherapy is to help the patient change his useless life goal to one of usefulness. This involves a radical reorientation that only the patient can make, for in the last analysis the therapist can not "cure" the patient, he must "cure" himself.

There are three steps in the psychotherapeutic

process. The first consists in the therapist's coming to an understanding of the patient, especially by discovering his life goal and style of life. An effort is made to see the patient's symptoms in the context of his personality structure as a whole. A variety of techniques make this possible, the principal one being the conversational interview. Therapist and patient sit facing one another in friendly conversation. Other techniques, usually employed as an integral part of the conversational interview, are the interpretation of dreams (both dreams during sleep and daydreams), free association, the study of childhood remembrances (especially the earliest remembrance of which the patient is capable), and the observation and interpretation of the patient's total behavior. In most cases an experienced therapist can complete the work of this first step in the first few interviews.

The second step in psychotherapy consists in helping the patient to understand himself, to know what sort of person he really is. An effort is made to assist the patient to see (1) that he has had a false orientation to life, (2) what that orientation has been, and (3) that he can develop a new and better way of looking at things. The techniques used by the therapist for diagnostic purposes are extended and developed in order to help the patient to gain these insights into his own nature. This second step is much more time-consuming than the first, for the patient's understanding of himself must be increased gradually. Blunt and authoritative pronouncements on the part of the therapist are not likely to be effective in the early stages of therapy, for the patient is not yet capable of dealing adequately with his problems on a conscious level.

In the third and final step in psychotherapy the patient is encouraged to make practical application of the insights he has attained. His efforts to be a useful member of society tend to result in the reduction and eventual disappearance of his disturbing symptoms and in a greater degree of genuine satisfaction and happiness than he has previously known. This stimulates the patient to make further efforts and helps to instill in him an attitude of courageously going about the business of solving his life problems.

These three steps in psychotherapy are not separated from each other in any absolute way—the first shades into the second and the second into the third. During the entire course of treatment the therapist maintains an attitude that is friendly and encouraging, but, in contrast to psychoanalysis, the development of a strong emotional bond between the patient and the therapist as a stage in the therapeutic process is not regarded as either necessary or desirable. The number of interviews per week varies from case to case, but is usually two or three. The duration of treatment varies greatly, averaging about three or four months and seldom extending beyond a year.

Individual Psychology as a Movement.—As an international movement individual psychology gives evidence of increasing vitality. Although its development was hindered in some of its phases by World War II, the years after the war have witnessed a widespread interest in it.

The movement's international organization is The International Society of Adlerian Psychology, with headquarters in Zürich, Switzerland. In the United States the national organization is The American Society of Adlerian Psychology. Local organizations exist in New York, Chicago, and

Los Angeles. National and local societies are also found in London, Paris, Amsterdam, Brussels, Zürich, and Vienna.

INDIVIDUALISM, in-dī-vid'ū-āl-iz'm, a regard for and emphasis of the individual. In the field of ethics, those doctrines which dwell upon individual welfare and are based upon the dictates of individual feeling. Under these views, it is taken for granted that if each individual seeks his own highest welfare, social welfare will take care of itself. Individualism is opposed to socialism and finds defense in the works of John Stuart Mill and Herbert Spencer. It becomes the duty of the state, under this conception, not to interfere with the individual except when it is necessary to preserve the opportunity for action. The function of the state is regarded as an artificial restraint, while individual initiative is a natural factor in evolution. See also UNITED STATES—44. *Way of Living* (American Heritage): American Individualism.

M., *Aspects of the Rise of Economic Individualism* (New York 1933).

INDIVIDUALITY, in-dī-vid'ū-āl'i-tē, a separate and distinct existence. The fact that one thing may be distinguished from all others gives individuality its meaning. Whether the distinction is only relative or is absolute is disputed among philosophers. The problem arises out of the difficulty of thinking of any distinctive character of an individual, except its location in space or time, without using general concepts. With Plato, the universals alone were real. With Aristotle, reality was found in the concrete individual and the universal stood only for an abstraction. The same problem occurs in medieval times, in the discussion of the relation of God, Trinity, and man, and in modern times in the question of the relation of the individual to society.

INDO-ARYAN LANGUAGES. See INDIA—9. *Languages*; LANGUAGES OF THE WORLD.

INDO-EUROPEAN LANGUAGES, the name invented by scholars to indicate a group of languages evidently related, that is, descending from a common ancestor language, of which we possess no direct record. The name Indo-European is inexact in both its components, since not all languages of Europe belong to this family, nor are the Indo-Aryan languages the only Indo-European languages outside Europe. Nevertheless, other terms, such as Aryan, Aryo-European, Indo-Celtic, and Indo-Germanic, though perhaps more correct, have not gained much foothold, at least in English-speaking countries.

The kinship of the Indo-European languages can still be seen quite clearly in some word classes, including numerals, family names, and names for the parts of the body: English *three*, *mother*, *foot* are obviously identical with German *drei*, *mutter*, *fuss*; with Latin *trēs*, *māter*, *pēs* (*pedis*); Greek *τρεῖς*, *μήτηρ* (Doric *μάτηρ*), *πούς* (*ποδός*); and Sanskrit *tráyas mātā* (accusative *mātāram*), *pāt* (accusative *pādam*). Sometimes the identity is not quite apparent to the eye, or rather ear, of the layman, but becomes immediately clear when a few simple rules, deduced from other equations, are considered: thus the correspondence of the initial *f* of English *foot*, German *fuss* with the *p* of Latin *pēs*, Greek *πούς*, Sanskrit *pāt*, is found also in many other words, such as English *father*, German *vater* (pronounced *fater*), Latin *pater*, Greek *πατήρ*, Sanskrit *pitā* (accusative *pitāram*); and English *fish*, German *fisch*, Latin *piscis*. On the other hand, Celtic loses initial *p* (English *f*, German *f*), and *fish* is therefore *iasc* (*a* is an epenthetic vowel), and *father*, *athir*, in Old Irish.

From the study of the original Indo-European material, discovered with the help of such rules as Grimm's and Verner's laws (qq.v.), the original vocabulary and therefore the original culture and home of Indo-European people before the separation can be deduced. The Indo-Europeans had no words for tropical or even Mediterranean products, plants, and animals, such as the laurel tree, the grapevine, the fig tree, the ape, the camel, the tiger, and the donkey; but they had words for northern animals and plants, such as the bear, the wolf, the cow, the goat, the pig, the goose, the apple tree, the oak, the beech, the birch, and the pine. Since they also had a name for snow, they obviously lived in a northern, cold climate; and this fact, as well as the names of some animals (especially the salmon) and plants, points toward the eastern shores of the Baltic Sea (Latvia and Lithuania).

The culture of the Indo-Europeans was very primitive, being in the Aëneolithic period, with little metal. They had a very modest form of agriculture that included the plow and some domesticated animals (the pig, dog, goose, cow, goat, sheep, and, later, the horse), but they lived mostly by hunting and fishing. Moreover, they had little acquaintance with navigation, very little industry, and almost no trade. They had of course no writing and counted no further than 100. All these conclusions are confirmed by the historical fact that in the whole Mediterranean and subtropical belt from Gibraltar to Calcutta, where ancient refined civilizations flourished, we see the Indo-Europeans

arriving as northern barbarians, destroying or assimilating previous native cultures (Minoan, Khattite, Babylonian, and so on), all belonging, it seems, to non-Indo-European peoples.

The Indo-European language was highly inflectional (English *boy: boys*); had vowel gradation (*gift, give, gave; song, sing, sang, sung*); distinguished sharply between the different parts of speech (especially the noun and the verb); had three genders (masculine, feminine, and neuter or inanimate: English *he, she, it*); had a constant agreement between adjective, noun, and pronoun; and had a special predilection for anomaly and "suppletivism" (English *I am: you are: I was: I have been; I go: I went*). All of these characteristics, however, tend to disappear more or less rapidly in all Indo-European languages, and English is a very good example, having departed further from the inflectional type than any other Indo-European language, with the possible exception of modern Persian. English has sharply reduced the endings (*I love, you love, we love, they love*), the vowel gradation (*love, I love, I loved, loved*), and the genders (which now find almost no formal expression except in some pronouns); the agreement between adjective and noun has disappeared entirely, and anomaly and suppletivism almost completely; and the distinction between the different parts of speech is weakening constantly, favored by the loss of the endings. *Dance, loan, bomb, cut, want, will, and love* are both nouns and verbs; in *I do not feel good* and *hit him hard*, the difference between adjective and adverb is lost; in *I distinguish good and evil*, the distinction between noun and adjective is disappearing; and *like* in colloquial English is a noun, a verb, an adjective, an adverb, and a conjunction. Such sentences as *I danced once with my wife* and *I shall not loan the book to Peter* are examples of an agglutinative, not an inflectional, language (the words *the, to, with, not, and shall* cannot be used independently); *I see you are well, I think we need money, we love wine, and I give Peter what I want* are sentences of an isolating language, for every word can be used in isolation (*we, love, what, wine, think, I, money*). The substitution in colloquial American, of *good* for *well* (in the phrase *I feel good*), of *me* for *I* (*it is me*), of *loan* for *lend*, and of *who* for *whom* shows the trend of the language away from inflection. Sentences like *He saw the geese and the oxen running away* and *He went out of his father's house* show remains of the inflectional type.

INDOCHINA, ĩn'dô-chĩ'nà, (1) the geographical name of the peninsula projecting from the Asian mainland between India and China; and (2) the political name of those parts of the peninsula that were colonial possessions of France and were therefore also called French Indochina. In the geographical sense, Indochina comprises, from west to east, Burma, Malaya, Singapore, Thailand, Cambodia, Laos, and Vietnam, which have a combined area of 795,148 square miles and a population (est. 1959) of 84,784,000. In the political sense, Indochina or French Indochina (Indochine Française) consisted of the three states of Vietnam, Cambodia, and Laos.

The name Indochina for this peninsula was introduced at the beginning of the 19th century

by the Danish-born French geographer Conrad Malte-Brun. Gradually it replaced the older names of Farther (Further) India in English and Inde Extérieure in French; in German, Indochina has become synonymous with Hinterindien. Charles Robequain, in his *Economic Development of French Indo-China* (p. 13, New York 1944), calls Indochina "a well-chosen name," pointing out that French Indochina "is only a part of the geographic bloc called Indochina," but the French habit of calling Indochine Française simply Indochine caused the term "Indochina" to become international usage in place of "French Indo-China." Since French Indochina no longer exists, the name Indochina should again designate only the entire peninsula, for which geographical, ethnological, and historical reasons make it both accurate and useful.

The Land.—The Indochinese Peninsula lies next to both India and China. This is true although Indochina is really a southern extension of the Chinese land masses. Three mountain ranges that originate in southwestern China and eastern Tibet run through the peninsula from north to south, connecting it with China, but not more closely than the ocean in the west connects it with India. One of these ranges separates Assam, India, from Burma, and another runs along the border of Burma and Thailand and on through the narrow southern arm of the peninsula that becomes Malaya. The third range is the Annamese Cordillera, which extends in a slightly southeasterly direction from Yunnan to southern Vietnam; several of its eastern arms run directly into the South China Sea.

The ranges determine the general north-south direction of the major rivers, which have formed and continue to enlarge Indochina's fertile deltas. From west to east these rivers are the Irrawaddy and the Salween in Burma; the Chao Phraya (Mae Nam or Menam) in Thailand; the Mekong, separating Thailand and Laos before it crosses Cambodia and South Vietnam; and the Red River, which flows from northwest to southeast through North Vietnam, rising in Yunnan and emptying into the Gulf of Tonkin (Tongking). The silt of these rivers and their flooding of the valleys and deltas contribute to Indochina's relative wealth, which consists in substantial surpluses of rice for export in Burma, Thailand; and Vietnam.

The productivity of the land is related to the climate, which is largely tropical and monsoonal with dry and wet seasons. While temperatures vary little in the south and as far north as the 20th parallel, their range is wide in the higher altitudes of the north. In the Mekong Delta and in Malaya summer and winter temperatures are only a few degrees apart, but in parts of North Vietnam and northern Burma, where the summer may be as hot as in the south, winter frosts are not infrequent. Over most of Indochina winter is the dry season, and summer the rainy season, but because of differences of topography and latitude the beginning and length of the two seasons and the amount of local rainfall vary in different regions.

The People.—Since prehistoric times the river valleys of Indochina have been migration routes for successive waves of immigrants from southern China and Tibet, many of whom were forced by later arrivals to move from the peninsula to the islands of Southeast Asia and the Pacific. The first inhabitants of Indochina are

thought to have been Negritos; remnants of these, akin to the Australian aborigines and the Papuans of Melanesia, can still be found in remote corners of the peninsula. The Negritos were followed by the Malayo-Indonesians, who still form the basic population stock in several Indochinese countries. A third wave of immigrants, whose movement began only in historic times, consisted of peoples of predominantly Mongolian race—those of Burma, who are probably of Tibetan origin; those of Thailand and Laos, who came from southwestern China; and the Vietnamese (or one of the branches that went into their racial formation), who are thought to have come from the lower Yangtze Valley. Because of these migrations, the population is both very diverse and very mixed.

In addition to the six more or less distinct leading nations (the Burmese, the Malaysians, the people of Thailand, their cousins in Laos, the Cambodians, and the Vietnamese), there exist in all parts of the peninsula countless numbers of so-called ethnic minorities. Most of these groups are not only different from the main body of the population, but also from each other. Often they consist only of small tribes. They speak a bewildering variety of languages and still lead on the whole very primitive lives.

Another strong element in the population picture consists of the Chinese, who are the largest minority group in several countries (Vietnam, Cambodia, Thailand, Malaya). Their occupational preference for trade makes them city dwellers, in contrast to the indigenous tribal minorities, who inhabit the remoter and more mountainous regions of the peninsula.

In general, the population of Indochina is relatively sparse. In Vietnam the density is approximately 221 persons per square mile; in Thailand, 110; and in Burma, 78. It is considerably lower in Laos, where 1,690,000 persons (est. 1958) live in a territory slightly larger than Great Britain.

HISTORY

The first known Indochinese states were Funan and Champa. They seem to have arisen at approximately the same time, Funan in the 1st century A.D. and Champa in the 2d century, and they owed their origin and high degree of civilization to Indian cultural penetration. By the 3d century, Funan had attained a commanding position over the south, center, and west of the peninsula, and through its seapower over other regions of Southeast Asia as well. Champa occupied the east coast of Indochina as far as the borders of China, which then extended south beyond the Red River valley, the home of the Vietnamese since the 3d century B.C. The populations of Funan and Champa were Malayo-Indonesian, and the culture of both states was entirely Hinduized. Funan, by far the larger of the two, barely survived the 6th century A.D. It was defeated and finally annexed by Chenla, a former vassal state situated in the northern part of the empire. Chenla's victory over Funan was the starting point for the rise of a new and even more powerful Indochinese state, the Khmer or Cambodian Empire. The power of Cambodia extended from Champa in the east over the entire center of Indochina far down to the southwest and up to the northwest, where the Malaysians and the Tibeto-Burmese, respectively, had begun to form several minor states. Cambodia reached the height of its power and of its cultural achieve-

ments in the 12th century, which saw the completion of Angkor (q.v.).

Meanwhile, in the northeast, Vietnam had become independent of China in 939. The Vietnamese, who, in contrast to the Hinduized Cambodians and Chams, were pupils of Chinese civilization, soon began to push southward. They expanded their country, first at the expense of Champa and later at that of Cambodia, along the east coast until they reached the Gulf of Siam. By the end of the 15th century, Vietnam had eliminated Champa and was threatening southern and eastern Cambodia, whose power and territory were also being reduced in the west by a newly arising Indochinese people. These were the Thai, who for centuries had been steadily moving from southwestern China into Indochina and, in the 13th century, had begun to form one of the strongest and most enduring of all Indochinese states, Siam (now Thailand). Siam grew quickly at the expense of Cambodia. It also extended its power far into Malaya and Burma and was prevented from ruling the entire peninsula only by the gradual rise of a strong Burma in the west, a powerful Vietnam in the east, and the refusal of certain Thai people in the north to accept Siamese rule. These northern Thai later formed the Kingdom of Laos. Between Thailand and Vietnam, Cambodia was slowly reduced to its present size, Vietnam acquiring the fertile regions of the lower Mekong Valley that later became known as Cochinchina. With the survival of several states in Malaya despite Thai pressure, the modern political map of Indochina had more or less taken shape by the mid-18th century.

From the beginning of the 16th century, however, Indochina had become more and more subject to European influences and interference. The Portuguese conquered and held for a while parts of the west coast, but they failed, as did the Dutch, English, and French in the 17th century, to gain a foothold in the east. Control of Indochina by the Western powers became a historical fact only in the 19th century. After three wars (1824-1826, 1852-1853, and 1885-1886), the British added possession of Burma to the previously conquered states of Malaya and the colony of Singapore. The French attacked and occupied eastern Indochina in several stages between 1858 and 1893. After World War II, in 1948, Burma regained its independence. Malaya became an independent member of the Commonwealth of Nations in 1957, and Singapore was made internally self-governing in 1959.

French Indochina.—After two centuries of peaceful interference in Vietnamese affairs—through missionary activities, attempts at trade, and assistance—the French began the conquest of eastern Indochina with an attack on Tourane, Vietnam, in August 1858. The attack failed, as did an attempt to conquer southern Vietnam in February 1859. Having barely been able to hold Saigon during the year 1860, the French undertook a new invasion of the south in 1861. Vice Admiral Louis Adolphe Bonard succeeded in joining the beleaguered French garrison at Saigon, in occupying three provinces adjacent to the city, and in inducing the Vietnamese emperor and court to sign a treaty through which Saigon and the three provinces were ceded to France (June 1862). After strengthening their Saigon base, the French imposed a protectorate on Cambodia in 1863 and annexed the remaining southern provinces of Vietnam in 1867. The occupied parts

of Vietnam became the colony of Cochinchina. An attempt to conquer northern Vietnam (Tonkin or Tongking) in 1873 failed, but a new, more powerful attack was launched in 1882. In 1883-1884, Vietnam was forced to sign treaties recognizing French protectorates over the north and center (the latter referred to as Annam).

These protectorates over Cambodia, Tonkin, and Annam soon proved to be legal formalities to disguise direct French rule. In 1887 they were combined with the colony of Cochinchina in the Indochinese Union and placed under a single governor general. The Kingdom of Laos was added to the French possessions in Indochina in 1893, and the territory of Kwangchow (Chankiang) was leased from China for 99 years in 1898, but the Indochinese Union became a political and administrative reality only under Governor General Paul Doumer. During his term of office (1897-1902), French Indochina received a centralized and modern administration as well as the means of systematic economic development and of exploitation of its resources. These resources lay chiefly in Vietnam and Cambodia, and consisted in a potential for a large rice surplus, in easily extractable deposits of coal and rare metals, and in the so-called red earth of the south, where the French soon developed profitable rubber plantations. Although French rule met with increasing nationalist opposition in the 20th century, French Indochina, with an area of 283,988 square miles, remained France's richest colony until the outbreak of World War II.

In 1940, after negotiations with the Vichy government, the Japanese were allowed to move into French Indochina, which they quickly turned into one of the main bases for their conquests in Southeast Asia. Shortly before their defeat they disarmed the French and allowed the Vietnamese emperor, Bao Dai, to declare Vietnam independent, but after the war the French returned to South Vietnam and Cambodia with British aid. French rule was gradually re-established, though incompletely, over the rest of French Indochina. In August 1945, nationalist forces had succeeded in forming a government in North Vietnam (Hanoi), which proclaimed Vietnam an independent republic, and in launching a vast resistance movement against the reimposition of French control. Although the Vietnamese national resistance movement was under strong Communist influence, because of military weakness the French recognized the government at Hanoi in March 1946. The breakdown of subsequent Franco-Vietnamese negotiations on the future status of Vietnam within the French Union led to war in Indochina, which lasted from December 1946 to June 1954. The Indochinese Union, which in 1946 became the Associated States of Indochina, consisted after 1949 of the three supposedly independent states of Vietnam, Cambodia, and Laos, but their independence was more nominal than real, and neither French military efforts, strongly supported by the United States, nor piecemeal political concessions were able to overcome Vietnamese national resistance. After the defeat of Dien Bien Phu in May 1954, caused largely by Chinese supplies for the Communist-led Vietnamese forces, France was ready to give up. This led to the Geneva agreements of July 1954, which put an end both to the war and to the existence of a French Indochina. Its population was then estimated at 31,460,000.

JOSEPH BUTTINGER.

INDONESIA, in-dō-nē'zhā, **Republic of**, a unitary state in Southeast Asia occupying all of the Malay Archipelago west of New Guinea and south of the Philippines, except the eastern half of Timor, a 950-square-mile enclave on the northwest coast of Timor, and the northwestern section of Borneo. Netherlands New Guinea, the western half of that island, is also claimed by Indonesia. Before independence was proclaimed in 1945, the country constituted the Netherlands East Indies.

Coat of arms of Indonesia.

The more than 3,000 islands composing Indonesia stretch 1,100 miles across the equator (5°30' north to 12° south latitude) and 2,800 miles between Asia and Australia (95° to 135° east longitude), and separate the Indian Ocean from the Pacific Ocean. The country has an area of 575,893 square miles, in six main physical divisions: Sumatra; Java (including Madura); Kalimantan (Borneo); Sulawesi (Celebes); Nusa Tenggara (the Lesser Sunda Islands, chiefly Bali, Lombok, Sumbawa, Sumba, Flores, and Timor); and Maluku (the Moluccas). With a population of 92,700,000 according to the 1960 estimate of the Indonesian National Planning Council, Indonesia is the sixth most populous country in the world. The populations of the larger islands were estimated as follows: Java, 58 million; Sumatra, 15 million; Sulawesi, 7 million; and Kalimantan, 4 million. The capital is Djakarta, known as Batavia while it was the capital of the Netherlands East Indies. The republic's motto is *Bhinneka Tunggal Ika* (Unity in Diversity). Its flag is red over white, and its national anthem is *Indonesia Raya*.

The present article is divided into the following main sections:

1. Political Divisions, Chief Cities, and Populations
2. The People
3. The Land
4. The Economy
5. Cultural Activities
6. Government and Politics

1. POLITICAL DIVISIONS, CHIEF CITIES, AND POPULATIONS

Politically, Indonesia is divided into 22 provinces, including two special districts, as follows:

PROVINCE	CAPITAL CITY
<i>Sumatra</i>	
Atjeh	Kutaradja
North Sumatra	Medan
West Sumatra	Padang
Riau	Tandjungpinang
Djambi	Djambi
South Sumatra	Palembang
<i>Java-Madura</i>	
West Java	Bandung
Central Java	Semarang
East Java	Surabaya
<i>Kalimantan</i>	
West Kalimantan	Pontianak
South Kalimantan	Bandjarmasin
East Kalimantan	Samarinda
Central Kalimantan	Palangkaradja
<i>Sulawesi</i>	
North Sulawesi	Manado
South Sulawesi	Makassar
<i>Nusa Tenggara</i>	
Bali	Singaradja
East Nusa Tenggara	Kupang
West Nusa Tenggara	Mataram
<i>Maluku</i>	
Maluku	Ambon
Irian Barat ¹	Soasui, Tidore Island

Special Districts

Metropolitan District of Djakarta-Raya (Greater Djakarta)

Special Autonomous District of Djokjakarta

¹ Includes claimed area of Western New Guinea (West Irian).

Some of the large cities of Indonesia, with their populations (1960 estimate unless otherwise noted), are: Djakarta (2,081,200), Surabaya (1,135,300), Bandung (951,900), Semarang (444,800), and Djokjakarta (Jogkjakarta, 1957 est., 289,400), all in Java; Medan (342,200) in Sumatra; and Makassar (357,400) in Sulawesi. Other important cities are: Surakarta (also called Solo), Malang, Tjirebon, and Bogor (formerly Buitenzorg) in Java; Palembang and Padang in Sumatra; Bandjarmasin and Pontianak in Kalimantan; and Manado in Sulawesi. In eastern Indonesia, Denpasar and Singaradja are the largest towns in Bali; Mataram in Lombok; Waingapu in Sumba; and Kupang in Timor. Of the commercial centers in Maluku, Ambon (Amboina) is the largest; Ternate off the western coast of Halmahera is second; while others, some historically important, are Tidore on Tidore Island, Bandanaira on Banda, Saumlaki on Tanimbar, Tual in the Kai Islands, and Dobo in the Aru Islands.

2. THE PEOPLE

Origins.—Although predominantly of Malay stock, Indonesians are of varied physical types, and their customs, clothing, ways of living, and folklore are even more diverse. The earliest Indonesians were of six different stocks and admixtures: Australoid, Melanesian, Negrito, and Veddoid, Papuan, and the so-called Alfur hybrid (Papuan and proto-Malay stocks intermixed). Today, most of the people representative of these archaic stocks inhabit eastern Indonesia or isolated interior areas of the larger western islands. Subsequent migrations came into the archipelago from Asia. The first Malays were the proto-

Malays (q.v.)—short, stocky, dark skinned, wavy haired, with Caucasoid features indicating their distant kinship with Europeans. The Mongol movement into southern Asia wrought changes resulting in the later, increasingly Mongoloid, deutero-Malay group, many of whom have the epicanthic fold ("slant-eyed" appearance) and more prominent cheekbones. Proto-Malays now occupy the interiors of the larger western islands of Indonesia and some of Nusa Tenggara, while deutero-Malays are coastal settlers. Further admixtures occurred as groups of Indians, Arabs, Chinese, and, most recently, Europeans entered the archipelago.

Composition.—The principal ethnic groups in each major region are: (1) in Sumatra: Atjehnese and Coastal Malay, Redjang-Lampung, Batak, Gayo-Alas, Menangkabau, and Kubu; (2) in Java-Madura: Sundanese, Javanese, and Madurese; (3) in Kalimantan: Coastal Malays, Javanese, Bugis or Buginese and others in coastal sections, with interior Dyaks or Dayaks divided into six tribal complexes (Ngadju, Bahau, Klemantan, Iban or Sea Dyak, Land Dyak, and Punan); (4) in Sulawesi: Macassar-Bugis (the largest group, southwest), Minahassa-Gorontalo (of whom the Manadonese are the best known; second largest group, northern), and the Toradja, Sadang, Mori-Laki, and Loinang (smaller groups in the center, southeast, and east); (5) in Nusa Tenggara: the Balinese and other proto-Malays on Lombok, Sumbawa, Sumba, and western Flores; (6) the ethnically diverse peoples of eastern Flores, Timor, and the Alor-Solor Islands; and (7) in Maluku: varied groups, including the Ambonese, with some European, Arabic, and Chinese infusions. The contemporary average Indonesian is short (about 5 feet 3 inches) and slender and has light-to-medium brown skin, straight or wavy black hair, a fairly flat face, a wide nose, and very little body hair. Estimates vary widely, but there are probably more than 100,000 Eurasians in the islands, while the principal alien minorities are Chinese (2 to 3 million), Arab (70,000), Indian-Pakistani (30,000), and several thousand Europeans and Americans, now including very few Dutch citizens.

Language.—The official language is Bahasa Indonesia, or Indonesian, developed from the widely used Coastal Malay, one of more than 30 native languages and 250 dialects belonging to the Malay-Polynesian linguistic stock. The only other important stock, Papuan, is spoken by tribes in easternmost Indonesia. The Indonesian language has absorbed contributions from Indian, Arabic, Dutch, English, and other sources, most recently in order to expand its cultural and technical usage.

Religion.—An estimated 90 per cent of the Indonesian people are Muslims, though Islamic practice has been influenced by pre-existing animism, Hinduism, and adat (customary law). More than 1 million people in Bali and Lombok have retained the once widespread Hindu-Buddhist religion and compose about 1.5 per cent of the population. Christianity, first introduced by the Portuguese in the 16th century, has been spread by many Protestant and Roman Catholic missionaries. The nearly 5 million (about 6 per cent) Indonesians who are Christians are most numerous in outer-island areas (Timor and Maluku to the east), in Minahassa in northern Sulawesi, and in northern Sumatra, center of the largest concentration of Christians, the Bataks.

Way of Living.—Regional characteristics of the Indonesian people vary widely because of cultural, linguistic, and other differences. An easy-going nature, a quickness to smile or laugh, a love of children, and an intense desire to assure the success of independence characterize most Indonesians. Home and family life is epitomized in innumerable small villages. Most cultural groups are patrilineal; the Menangkabau of Sumatra are Islamic and matrilineal. In urban areas, people of similar cultural backgrounds (Javanese, Batak, Chinese, and so on) tend to cluster together. Rice is the staple food, usually with fish or vegetables for protein and sharp pepper for flavor. In some regions maize, sweet potatoes, sago, bananas, or other starches replace rice. Chickens, ducks, or goats supply meat, though non-Muslims eat pork, and beef is used particularly for feasts. Tea and coffee, and sometimes coconut, chocolate, and goat or cow milk are the major beverages. Cigarette smoking and *sirih* or betel-nut chewing are widespread.

Characteristic clothing for women is the *kain* (sarong) and *kabaya* (fitted blouse with long sleeves); for men, *kain* in rural areas or on religious days, fezlike *pitji*, and, in cities, Western trousers and shirts. Regional variations are numerous, in urban areas, Western clothing is increasingly common. Married women usually wear their hair in a bun; unmarried girls braid their hair in pigtails or wear it long, but Western styles are also seen.

Soccer football, badminton, and volleyball are the most popular sports, but interest in swimming, tennis, and basketball is increasing. Student, religious, labor, and other organizations frequently participate in parades honoring people or events; and for many decades, until it was disbanded in 1961, the boy scout movement was an outstanding part of Indonesian life.

Health.—Health problems are still serious in the nation. Malaria and tuberculosis each cause about 10 per cent of the deaths, with yaws the third most serious illness. Trachoma, dysentery, leprosy, and typhoid are also widespread. Most disease in Indonesia is attributable to overcrowded housing, undernourishment, general poverty, debilitation from other diseases, and shortages of public health facilities and doctors. Despite a 2 per cent annual population increase, Indonesia's infant mortality rate may be as high as 150 per 1,000 live births.

3. THE LAND

Physical Character.—Geologically, the Indonesian archipelago has three sections: (1) the Sunda Platform, a southeastern extension of ancient Eurasian structures, formerly above sea level, now underlying Sumatra, Java, Kalimantan, and the shallow waters between them and the Asiatic continent; (2) the Sahul Shelf, the northernmost section of the ancient Australian Shield, also above sea level in recent geologic time, supporting the eastern islands and New Guinea; and (3) an intermediate area, including the western islands of Nusa Tenggara, Sulawesi, and some of Maluku, all rising out of deep waters that were once part of a broad strait separating the enlarged Asiatic and Australian continents. Wallace's line (see WALLACE, ALFRED RUSSEL) and Weber's line, running through the intermediate area, mark the transition between Asiatic and Australian flora and fauna.

Indonesia's topography is one of marked con-

trasts. The most extensive mountain system extends from northern Sumatra southward near its west coast and curves eastward across southern Java to Nusa Tenggara. The section in Sumatra known as the Barisan Mountains rises to 12,467 feet at Mount Kerintji, south of Padang. Lesser ranges sweep northward across Kalimantan, Sulawesi, and Maluku. Indonesia has more than 100 active or recently active volcanoes, most of them part of the major mountain system. Lake Toba, Indonesia's largest freshwater lake, occupies a huge extinct volcanic *caldera* in northern Sumatra. The most famous volcano is the tiny island of Krakatau (q.v.), in the Sunda Strait between Sumatra and Java, which erupted explosively in 1883. Broad plains lie east of the Barisan Mountains in Sumatra, north of the volcanic mountains in Java, and in several parts of Kalimantan. Elsewhere, most level land is found on coastal fringes of mountainous islands. Waters are shallow in the Strait of Malacca between Sumatra and Malaya, in the Karimata Strait separating Kalimantan and Sumatra, in the Java Sea on the Sunda Platform, and on the Sahul Shelf in eastern Indonesia; but deep waters are characteristic of the Indian Ocean and the narrow seas, including Makassar Strait between Kalimantan and Sulawesi, of the central archipelago. The longest rivers are the east-flowing streams of Sumatra with headwaters near the western coast and those of Kalimantan rising in its north-central mountains.

Climate.—Located astride the equator, Indonesia has a tropical marine climate, having at sea level uniform, high temperatures, high humidity, and moderate to heavy rainfall. Seasonality results from changes in wind patterns and directions. The average monthly temperature ranges between 77° and 81° F.; the average daily temperature fluctuates between 70° and 90° F.; and the absolute range is 61° to 97° F. Most of western and northern Indonesia is characterized by a tropical rain forest climate with average annual rainfall of more than 80 inches. Eastward from central Java a savanna or tropical wet and dry climate prevails, with decreased annual rainfall and increased variability as to total rainfall and length of dry season. Throughout Indonesia, amount of rainfall, temperature, and humidity vary with elevation, winds, and distance from the coast. The Asiatic or west monsoon is strongest close to the continent; the Australian monsoon influences eastern Indonesia. The decrease of temperature at increased elevations is shown in Java, where at Djakarta (coastal) the average annual temperature is 78° F.; at Bogor (800 feet), 75°; at Bandung (2,300 feet), 71°; and at Tosari (5,800 feet), 61°. Highlands near populous lowlands provide temperature relief, with cooling air drainage, and have accessible places to visit; they are densely populated in parts of Java and Sumatra.

Natural Resources.—Most of the soils of Indonesia are thin latosolic soils developed under rain-forest conditions and subject to rapid leaching and erosion when cleared for cultivation. The most valuable are the fertile soils derived from basic volcanic rocks, some limestone soils, and stream-deposited alluvium, notably in Java (where most of the population is concentrated), in the plantation lands of northeastern Sumatra, and in northern Sulawesi (Minahassa District).

Two thirds of Indonesia is covered by rain forest (240 million acres), which predominates

throughout the western and northern islands, grading into savanna (parklike clumps of trees and grassland) toward the southeast. The estimated forested area in Java is 23 per cent; Sumatra, 60 per cent; Kalimantan, 77 per cent; and eastern Indonesia, 50 per cent. As many as 3,000 families of plants grow in the archipelago, with considerable local variety. The typical coastal forest consists of mangrove trees grading into a narrow belt of nibong or nipa palms, with a broad belt of coastal swamp and upland forest farther inland, including many commercially valuable Dipterocarpaceae species. With increasing elevation, subtropical to temperate zone mountain forests, including stands of pine and conifers, predominate, while mountain mossy forests occupy the highest lands. Bamboo and rattan, in a wide variety of types, are major plants throughout Indonesian forests.

Animal life, also varied, is characterized by both Asiatic and Australian influences. Elephants, tigers, wild boar, leopards, rhinoceroses, and many varieties of monkeys and apes, including the orangutan, are found in the western islands. Marsupials, similar to those of Australia, are in great variety in eastern Indonesia. Smaller animals include tapirs, deer, wild pigs, squirrels, lemurs, bats, and flying foxes. Crocodiles are plentiful in rivers, while snakes, such as the python, and lizards—some as small as the household insect-catching *tjetjak* and others up to 10 feet long—are prevalent. The abundant insect life includes most varieties of mosquitoes; white, black, and red ants; spiders; scorpions; and the praying mantis (and related walking leaf and walking stick). Birds include the pheasant, pigeon, peacock, and bird of paradise, parrot, kingfisher, duck, and cockatoo. Both freshwater and sea fish, such as the tasty *kakap*, mollusks, crustaceans (*udang* or shrimp), sharks, and octopuses, are plentiful.

WILLIAM A. WITHINGTON,
Assistant Professor of Geography, University of
Kentucky.

4. THE ECONOMY

The history of the Indonesian economy in the first decade of political independence should be viewed against a background of low levels of material welfare and economic resources, decades of colonial economic domination, and eight years of military occupation and war. Annual per capita income was about \$100 or below, and there was no clear evidence of a secular rise over the decade. About 80 per cent of the population earned a livelihood in the agrarian sectors, which use relatively little capital. Approximately 48 million rural people live on the 21 million arable acres of fertile soil on the islands of Java and Madura—averaging less than one half acre per person. Conditions on the outer islands are more favorable, but the costs have hitherto proved too great for extensive transmigration from Java, which remains the most densely populated large area in the world.

The small manufacturing sector, which unlike the agricultural sector uses capital intensively, accounted for only about 8 per cent of gross domestic product. The small size of this sector—a legacy of the colonial economy discussed above—is perhaps the most important indication of low levels of capital resources and entrepreneurial and technical skills. Moreover, even as late as 1940 only 37 Indonesians graduated in that

year from colleges and 240 from high schools set up by the Dutch in Indonesia.

Nationalism in the economic sphere in the 1950's had defined the major goal of economic policy: "sweeping away the vestiges of colonialism" and moving "from colonial economy to national economy" through "Indonesianization." The pressure on Dutch and Chinese business interests gradually increased, for instance, with the nationalization of the formerly Dutch-controlled Java Bank in 1953, with the preferences granted to Indonesian businessmen (as against foreigners) in the distribution of credit and import licenses, and with the abrogation of the Round Table Conference guarantees of Dutch investments in 1956. Then, in December 1957 virtually all Dutch enterprises were taken over, a somewhat unexpected climax to the violent agitation protesting the Netherlands' continued control of West New Guinea. The Indonesian government refused to discuss compensation for these properties (valued at approximately \$1 billion) until the West New Guinea question was negotiated.

The loss of a managerial and technical elite—about 45,000 Dutch persons left Indonesia following the 1957 take-overs—and the unexpected loss of Dutch-owned ships which carried 70 per cent of interisland trade (the Dutch owners succeeded in removing them from Indonesian control) had serious repercussions on the Indonesian economy, as did the disruptions of the 1958 rebellion.

The Chinese business community, always the object of nationalistic antagonism, suffered its first large-scale setbacks at the hands of the Indonesian government in 1958 and 1959. Because of alleged Kuomintang complicity in the 1958 rebellion, the government took over all businesses and organizations of the Kuomintang-affiliated Chinese, who numbered at least 100,000. A take-over followed in 1959 of some portion of the small traders and businesses operated by aliens, mainly Chinese, in most rural areas of Indonesia, a measure which in theory applied to upwards of 25,000 small businesses. Thus, in the period 1957–1960, economic nationalism produced what is perhaps the most important change in the Indonesian economy since 1945: replacing primarily alien control, in the "modern" economic sectors, with Indonesian control, replacing private ownership with public ownership. Enterprises remaining under foreign ownership included American private investment of more than \$500 million, concentrated in petroleum extraction.

By late 1958, the era of extensive government support to nascent Indonesian capitalists had passed. The former Dutch firms were placed under government ownership and management, and the stronghold of the indigenous capitalist, the import trade, was made a virtual state monopoly. The position of private entrepreneurs in Indonesia's socialist order was not precisely defined, but under the government regulations of April 1960 they were apparently to be largely subordinated to direct government regulation.

Serious shortages of the staple food, rice, occurring intermittently as in 1956 and 1958, were alleviated by large increases in rice importation, which sometimes equaled 10 per cent of annual domestic rice production (7-8 million tons). These shortages, mitigated only partially by United States surplus agricultural commodities assistance, necessitated the dangerous depletion of scarce foreign exchange reserves to finance rice imports. Beginning with the Agrarian Law of October

UPI Photo

A modern oil refinery at Balikpapan, in eastern Borneo.

1960, the government hoped to redistribute land-holdings, thereby diminishing inequity and exploitation, and encouraging greater production through a wider base of ownership. The most important provision of the law was that no landholding should be less than 4.94 acres. Family holdings might be as large as 49.4 acres, the limit being determined by the number of dependent family members.

An eight-year plan, announced in August 1960, which set an extremely high target level of investment of about 15 per cent of national income, required more than doubling the investment rate of the most prosperous past years.

The shortage of domestic savings for financing rehabilitation and development has led the Indonesian government to accept extensive economic assistance from foreign governments. The total negotiated amount of foreign government economic assistance to Indonesia during the 1950's was more than \$1.5 billion—approximately half of which was utilized before 1960.

United States economic aid to Indonesia—loans, grants, and sales—totaled \$467 million between 1950 and 1960. Economic aid from Communist countries, begun in February 1955, totaled \$368 million by February 1960, most of which was still in the negotiating and planning stages. American economic aid emphasized technical training of indigenous personnel and social overhead capital—transport, power, communications. Communist aid, by contrast, stressed building of industrial plant and equipment.

Western European countries had loaned \$132 million to Indonesia up to January 1959. Japan and Indonesia agreed in 1958 on a World War II reparations payment totaling \$800 million, to be paid in loans and grants during 1958–1970.

Several hundred Indonesian military officers, beginning in 1951, received training under United States military aid programs, but Washington refused to provide substantial military equipment until after the Soviet Union had begun providing military equipment to Indonesia in 1958. By 1961 the Soviet Union had replaced the United States

Indonesia: Principal cities, products, and resources.

as the major supplier of equipment to the Indonesian armed forces.

In agricultural production for domestic consumption, rice predominates. Corn, cassava, sweet potatoes, peanuts, beans, squash, soybeans, sago, and coconut are also grown. The Western- and Indonesian-owned agricultural estates produce, mainly for export, rubber and sugar along with copra (dried coconut meat), coffee, tea, cinchona (for making quinine), tobacco, palm oil, kapok, cocoa, and various spices. The principal livestock for slaughter are cows and sheep; water buffalo, cows, and oxen are bred for draft animals.

The most important mineral extraction is of petroleum (on Sumatra, Java, Borneo, and Ceylon) and tin (on Bangka, Belitung, and Singkep). Bauxite and coal are mined in considerable quantities, along with small quantities of gold, iron ore, asphalt, manganese, copper, nickel, sulphur, and iodine.

DONALD POND,
Cornell Modern Indonesia Project, Cornell University.

5. CULTURAL ACTIVITIES

Education.—The expansion of education at all levels since independence is impressive. In 1958 there were more than 8 million students; 7.3 million in primary schools; 754,000 in secondary and vocational schools; and 38,000 in institutions of higher learning. More than 9 million people had received certificates from adult literacy schools. Literacy in Indonesia, estimated at 7 per cent in 1948, rose to 60 per cent by 1960. Regional languages and Indonesian are used in primary education; Indonesian in secondary schools, where English, the official second language, is introduced; and Indonesian, sometimes with English language textbooks or lectures, in higher education. The oldest institution is the University of Indonesia, consisting of a faculty of engineering (now the Technical Institute) founded in 1919 at Bandung, faculties of law (1924), medicine (1927), letters (1940), and economics at Djakarta, faculties of agriculture and veterinary science (1948) at Bogor, and several other faculties. Among six other state-sponsored institutions, the largest is Gadjah Mada

University, founded at Djokjakarta in 1949, with 13 faculties and 10,000 students. The others are Padjadjaran University (Bandung), Airlangga (Surabaya), Andalas (Bukittinggi, Sumatra), University of North Sumatra (Medan), and Hasanuddin (Makassar). Many of the private universities are associated with religious organizations. Teacher-training schools and many universities receive support from organizations of the United Nations, the Colombo Plan, the United States International Cooperation Administration, Ford and other private foundations, and missionary organizations.

Few large libraries exist in Indonesia. The leading ones are the former Royal Batavian Society of Arts library in Djakarta, a number of technical, research, and municipal libraries, the British and United States information services libraries, and several rapidly expanding university libraries. The principal museum, at Djakarta, houses Oriental art and ethnographical exhibits. The most notable of the other museums and parks are the Botanical Gardens at Bogor, established in 1817, housing many species of tropical vegetation and a presidential palace dating from the 18th century.

Architecture and Painting.—The architecture of Indonesia reflects its complex intermingling of cultures. The most impressive religious architecture was built in central Java: the Borobudur (q.v.), an 8th century Buddhist stupa; and the shrines at Prambanan, which represent the culmination of Hindu culture. Mosques reflect Middle Eastern influences and temples reflect early cultural contact with the Chinese. Most of the larger buildings indicate European sources. Many modern buildings have adapted regional forms, such as the gracefully distinctive saddle-shaped roofs and architecture of the Minangkabau or Batak peoples.

Two traditions intertwine in Indonesian painting: folk art and Eurasian art. Highly stylized Hindu-Indonesian folk art, depicting scenes of the great Hindu epics, has persisted for centuries in the villages, especially in Bali. Educated in Europe, Raden Saleh (1816–1880) was the first important Indonesian painter to use Western techniques. During the early 20th century, the

East Indian school evolved, focusing on the exotic appeal of Indonesia's landscape. The establishment in 1938 of the Association of Artists (PERSAGI) marked the beginning of truly national development, emphasizing self-expression. During World War II, the Japanese organized artists for propaganda purposes, and thereby contributed to their development. Among them Af-fandi (1910-), whose work is sometimes suggestive of German expressionism, is considered most accomplished. Since 1945 the principal art centers have been Djakarta, Bandung, and Djok-jakarta, where O. Effendi, Derachman, and Zaini have been leaders. Made, Reding, Tedjiwa, and Gendjot on Bali use a closely concentrated art form depicting rural scenes and people.

Music and Dance.—The highly sophisticated music of the *gamelan* orchestra is the traditional music of Java and Bali. It is characterized by scales of five notes each. Gamelan orchestras are used in traditional ceremonies and especially as accompaniments to *wajang* dances and puppet plays performed behind screens upon which shadows of the puppets are projected. These orchestras are composed largely of percussion instruments (gongs, drums, and xylophone- and marimbalike instruments) and are usually accompanied by singing. String and wind instruments are less prominent. Other traditional instruments used in outer islands include the *angklung* (a bamboo shake instrument), flutes, and various percussion and stringed instruments. Western instruments, especially the guitar, are now widely used to accompany folk dances and popular singing.

Among dances characteristic of Indonesia, those of Bali and Java are most popular. Performers wear traditional costumes and use highly stylized gestures and facial expressions similar to those shown in Hindu sculpture. Bali dances include the *legong*, performed by three girls; the *ketjak* or monkey dance; the solo *kebyar*; and the *djanger*, including both boys and girls. Typically Javanese are the *serimpi*, performed by four girls of noble birth (central Java); the *wajang orang*, a puppet dance (Surakarta); and the *tari topeng* (mask dance of west Java). Many other dances are indigenous to Sumatra, Kalimantan, Sulawesi, and eastern Indonesia.

Handicrafts.—Among the most striking handicrafts of Indonesia are the textile arts. Each region weaves its own distinctive cloth for daily or ceremonial wear, the latter often richly interwoven with gold thread. The batik or battik (q.v.) technique and the *ikat* technique (a process in which the threads are dyed before weaving to form a pattern) in central Java are unique. Woodcarving is highly developed in Japara (Djepara, central Java) and Bali. Besides utilitarian bowls, platters, and chests, figures of animals, people, ancient gods, or heroes, and masks for dancers are produced. Silverwork is a specialized craft in Djokjakarta, Java, Sumatra, southern Sulawesi, and Bali. Jewelry, utensils, and ornamental containers of intricate design are wrought, sometimes in silver filigree. Other handicrafts include weaving of baskets, sleeping mats, hats, and bags from rattan, palm leaves, and bamboo strips; beadwork to decorate bags, belts, and ceremonial ornaments or garments; leatherwork, frequently using alligator, snake, or lizard skins, for shoes, carrying cases, and other products; and ivory or horn, worked to make handles and sheaths of daggers, knives, and swords, and

small carved articles. Lamps, cooking utensils, and chests are made of brass, copper, iron, and aluminum, sometimes combined with wood.

Theater and Cinema.—The Indonesian theater consists primarily of the Hindu epic dance dramas. Most of the films shown are foreign, the majority coming from the United States, but with increasing numbers coming from Europe, the Soviet Union, and Asia. The Indonesian film industry began in 1950. During the 1950's, 8 studios and about 15 producers were making films accounting for 15 per cent of the screen time.

Literature.—The earliest Indonesian novels, published in the 1920's, were written by Merari Siregar (*The Miseries of a Young Girl*, 1922), Marah Rusli, and Abdul Muis. Indonesia's writers gained experience largely through journalism, and most of them still work as journalists. A Djakarta periodical, *Pudjangga Baru* (New Writers), started in 1933, supplied a name for the period of the 1930's. Its founders comprised two factions, one looking toward European, especially English, literature and the other toward Asian traditions. Amir Hamzah was the leading poet; Armijn Pané, the outstanding novelist of realism (*Shackled*, 1940); and Sanusi Pané, the most important playwright (*The New Man*, 1940). In the 1930's in Medan, an Islamic intellectual movement, coming from a less sophisticated background than that of the Djakarta writers, produced works emphasizing social progress, nationalism, and religious revival based on works in Arabic. A self-educated pro-Marxist group focused on problems of the proletariat. The Japanese occupation marked a period of transition, with academic titles tending to replace feudal titles as marks of status. Chairil Anwar, who died in 1949, was maturing as a poet of the Indonesian language. Also important were Usmar Ismail (plays, poetry), Rosihan Anwar (poet, newspaper editor), Abu Hanifah, Amal Hamzah, and Anas Ma'ruf. During the late 1940's a group of writers known as the "generation of 1945" emerged. Mochtar Lubis was among the most versatile of this group as a short story writer, novelist (*There Is No Tomorrow*, 1948), journalist, and editor (*Indonesia Raya*, 1950 to his house arrest in 1956). Others included Asrul Sani, Idrus, Pramoedya Ananta Toer (*The Guerrilla Family*, 1950), and Achdiat K. Mihadja (*The Atheist*, 1949). Too busy earning a living to concentrate on writing, most writers have turned to the short story. In 1959, Indonesia had 94 daily newspapers with a total circulation of over a million. See also JAVANESE—Literature.

WILLIAM A. WITHERINGTON.

6. GOVERNMENT AND POLITICS

Sovereignty passed to the United States of Indonesia on Dec. 27, 1949 and the army, youth groups, and secular nationalists quickly forced the dissolution of the Dutch-made *adat*-based member states, most of which were absurdly artificial, so that on Aug. 17, 1950 the restored unitary Republic of Indonesia was proclaimed, the fruit of five years of revolutionary struggle. But Indonesia was immediately faced with many complex political problems.

The government's attempts to channel the vast energies unleashed by the revolution in a constructive direction, and to modernize the highly heterogeneous and uncoordinated state bureaucracy met with little success. The political necessity of finding jobs for thousands of ex-revolutionaries

Freedom Palace, the stately presidential residence, in Djakarta, the capital city.

H. Armstrong Roberts

swelled an already unwieldy and undertrained civil service. The exigencies of the military struggle against the Dutch had prevented the imposition of effective central control over local and regional nationalist leaders. Inevitably, after the revolution, these regional authorities, though sincerely nationalist, were not eager to subordinate themselves to a centralized Djakarta-based regime.

Moreover the army, which had come to regard itself as the spearhead of the revolutionary regime, was unwilling to act simply as the obedient, nonpolitical servant of a rather humdrum civilian parliamentary government. The widespread decline of revolutionary unity and dynamism in Indonesia after 1950 deprived radical youth groups and other revolutionary elements of their *raison d'être*. And President Sukarno, with his vast energies, talents, and popularity among the common people, chafed under the largely ceremonial responsibilities which the parliamentary system assigned him.

As a result of these difficulties, a severe political crisis soon developed. Attempts to purge the army of revolutionary-minded but technically inefficient elements led to the so-called October 17th Affair, late in 1952. The Western-oriented group of politicians and army officers behind the purge tried to dismiss a recalcitrant Parliament by force, and suffered a decisive defeat when the president appealed to the public over their heads, and a rapid series of regional military coups took place in support of his action. The crisis seriously damaged the prestige and moral authority of the hitherto dominant section of the revolutionary elite, and exposed the fragility of the parliamentary system to many who were already dissatisfied with it. It also revealed the true political strength of the president and the army, who were thus encouraged to push forward to the center of the political arena, where the political parties had previously held sway.

The most important of these parties in the early parliamentary period were: (1) the Council of Indonesia, the Masjumi, consisting largely of modernist Islamic groups drawing strength from small-scale private business; (2) the Socialist Party (Partai Sosialis Indonesia, P.S.I.), a small elite group of highly influential Westernized intellectuals and politicians; (3) the Religious Teachers Party (Nahdatul Ulama, N.U.), an association of traditionalist, Javanese Islamic groups, with few strong ideological commitments,

but powerful because of its "swing" position in the center of the political spectrum; (4) the Nationalist Party (Partai Nasional Indonesia, P.N.I.), a Java-based mélange of civil servants, aristocratic *adat* elements, radical intellectuals, and prewar followers of President Sukarno, with whom the party closely identified itself in this period; (5) the Communist Party (Partai Komunis Indonesia, P.K.I.), also largely Javanese, based on a network of labor and peasant organizations, and, by 1953, largely recovered from the disastrous Madiun uprising.

The over-all trend in Indonesian party politics, at least until 1957, was a gradual leftward shift in the political center of gravity, as the early cabinets, dominated by a Masjumi-P.S.I. coalition, proved unable to cope with Indonesia's problems—at least over their rivals' opposition. One important landmark therefore was the formation in 1953 of Ali Sastroamidjojo's first government, from which the Masjumi and the Socialists were excluded. The new cabinet, composed mainly of P.N.I. and N.U. politicians, depended frequently on the support of the president and the Communists. The policies of the new ruling group differed from its predecessors' in two striking respects. In the economic field, it actively encouraged the development of an Indonesian business class, at the expense of Dutch interests. In foreign affairs, it veered sharply away from the cautiously pro-Western policy of the Masjumi and the P.S.I. to one of "positive neutralism" and a sustained effort to increase Indonesia's prestige and influence in the international world. The Afro-Asian Conference, held by Premier Ali's invitation at Bandung in the spring of 1955, was a triumphant climax to this campaign.

In its turn the new cabinet aroused considerable discontent. Its patronage policies hastened a secular decline of administrative integrity, and heightened a continuing struggle for power between the politicians and the professional bureaucracy. Economic policies, which inevitably appeared to favor overpopulated Java, helped to augment rising anti-Javanese sentiment, which had been largely latent during the revolution. The cabinet's attempts to tighten its grip on the discontented outer regions by administrative centralization (which benefited the predominantly Javanese civil service at the expense of local authorities) were strongly resented. The government's often openly political appointments and promo-

Roofed, gaily painted native craft swarm the Musi River at Palembang, Sumatra.

tions within the army angered the high command. In the end, an army, not a parliamentary, opposition brought the cabinet down.

Nevertheless the parliamentary system survived, largely because many of those dissatisfied with it felt that it could not be condemned completely before nationwide elections had been held. The existing Parliament, with its large contingent of Dutch-appointed "Federalist" members, was generally regarded as unrepresentative and opportunistic. It was hoped that an election would simplify the party system, permit the formation of a dynamic and unified cabinet, and revive political morality and morale. Activist youth elements, alienated by the routine atmosphere of postrevolutionary life, found a new outlet for their energies and passions in the hotly contested year-long election campaign.

The elections, held late in 1955, unfortunately aroused exaggerated expectations. Though conducted with remarkable efficiency and fairness, the results did little to change the party system. While the Socialists suffered a crushing defeat, the Masjumi, the P.N.I., the N.U., and the Communists emerged with between one sixth and one fifth of the vote apiece. The Masjumi was shown to be the only party with substantial strength outside Java.

Mr. Sastroamidjojo's second cabinet, formed in the wake of the elections, was a decided anticlimax. All the familiar faces reappeared. The highly precarious coalition of antagonistic Masjumi and P.N.I. politicians was only too clearly a marriage of convenience against the growing power of extraparlimentary forces. Reactions were not slow in coming. Beginning in August 1956, a succession of coups, counter coups, and attempted coups in Java, Sumatra, Kalimantan, and Sulawesi reduced the government to almost complete paralysis.

By late 1956, a widespread feeling of frustration and deep discontent with the existing political system and the disastrous economic plight of Indonesia had undermined the prestige and morale of the parties, and simultaneously encouraged the ambitions of the army, and other antiparlimentary forces. President Sukarno found eager listeners therefore when, in February 1957, he announced his advocacy of a new political system—"guided democracy." This system called at first for an all-party national-unity cabinet including the Communists, working under the guidance of a national council, presided over by the president. The reaction of the non-Communist parties was naturally unenthusiastic. Accordingly Sukarno, in temporary alliance with the army leadership, took the cabinet's inability to solve the military and regional crisis as grounds for declaring martial law all over Indonesia. The local military commanders thus assumed virtually complete power in their areas. And in the capital, the president formed his own "nonparty" cabinet.

In itself the move did nothing to solve the general *crise de régime*, in which ethnic antagonisms, economic interests, religious animosities, ideological rivalries, and personal enmities were inextricably intertwined. Communist successes in the Java provincial elections held in the summer of 1957 increased internal tension and anxieties, particularly in the largely anti-Communist Outer Islands. An attempted assassination of the president and threats of mob violence against opposition Masjumi, Socialist, and other regional leaders in Djakarta were symptoms of a rapidly deterio-

rating situation which culminated in the outbreak of rebellions in Sumatra and Sulawesi in February 1958.

The effective military measures taken by Djakarta rapidly reduced the rebels to intermittent guerilla activity in the hinterland of Sumatra and Sulawesi. While the prestige of the president and the army were increased by their victory, the involvement of prominent Masjumi and Socialist leaders in the rebellion undermined their parties' political power, and led eventually to their proscription.

Three major centers of political power remained in the wake of the rebellion. Under martial law, the army assumed many of the powers and functions of the civilian bureaucracy. The expropriation of Dutch business assets in December 1957 allowed the army to move in and take control of a vast economic empire. While the N.U. and the P.N.I., ill adapted to Indonesia's new nonparliamentary form of politics, retired into the background, the Communist Party continued to rival the army's power, since it was tightly organized, ideologically cohesive, and undiscredited by corruption and previous tenure of governmental power. But it was President Sukarno, with his unique hold on the imagination of the common people, who remained the single most important political force in Indonesia, though his power was partly a function of his mediating position between the army and the Communists.

The reinstitution on July 5, 1959, of the Republican Constitution of 1945, granting the president near-dictatorial powers, merely added to the legitimacy of Sukarno's dominant position. The presidential palace, not Parliament or the cabinet, was the place where the major political decisions were made. A new, presidentially appointed Parliament showed little sign of life. In foreign affairs the new regime continued to develop the policy of nonalignment with either of the major world powers, and evinced an unprecedented determination and energy in pressing Indonesia's claim to sovereignty over Dutch-controlled western New Guinea. Internally, it was attempting to solve Indonesia's problems, and radically "retool" her entire political, economic, and social system within the centralized, authoritarian, and dynamic framework of "guided democracy."

7. HISTORY

Indonesian history falls into two very distinct phases. In the first of these, which runs from the early centuries A.D. up to the late 19th century, the huge distances of the archipelago, the small population, and the comparatively simple technology made it impossible for the area to enjoy any real degree of economic interdependence or political unity; the most one can say is that most of the islands were subject to the same external cultural influences and that certain parallels in the cultural patterns and economic and political history of the different parts of the archipelago are observable. In the second phase, beginning in the late 19th century, the impact of modern Western technology, organizational forms, and ideologies, associated with a huge increase in population, brought about the political unification of the area under Dutch rule and set the stage for the transfer of power to Indonesian hands.

Recorded history in the Indonesian islands begins in the first centuries A.D. with the coming of a wave of Indian cultural influence, the first of three such waves which have played a decisive part in Indonesian history. It is most probable that this Indian culture, Hindu or Buddhist, was first adopted by petty kings in many parts of the archipelago, who gained from it both magico-religious legitimation and practical tools—writing and bureaucratic techniques—on which they could build larger political units. Later this imported culture spread slowly downward in society, but it is significant that it pushed down deep roots only in areas of intensive wet rice cultivation, chiefly in the present day Javanese-speaking areas of Central and East Java.

In the 7th century appear the first larger Indianized states, Srivijaya, centered near modern Palembang, and a series of dynasties in central Java. Buddhist Srivijaya, which lasted until the 13th century, was the first example of one of the two main types of Indonesian states, a coastal principality, directly ruling only a small population, living on trade and naval power. Its fortunes, like those of its successors, depended thus on the fluctuations of, and balance of naval power along, the great Asian trade route which has flowed intermittently for two millennia through various parts of the archipelago on its way between China and India and on to the Middle East and Europe.

On the other hand, the central Javanese dynasties, like their successor states in Central and East Java, in areas of relatively large-scale wet rice cultivation, were based on bureaucratic or feudal control of land revenue and a large peasant labor force, such as was necessary to build the immense 8th century Buddhist shrine of Borobudur and the 10th century Hindu temple complex of Prambanan. The fortunes of this type of dynasty depended more on internal factors, chiefly its ability to keep subordinate lords, the Hindu and Buddhist and later Islamic orders, and peasants under central control.

From the 10th to the 14th century the seat of dynastic power on Java shifted to the east, to the Brantas River valley near modern Surabaya, culminating in the empire of Majapahit which in the 14th century controlled much of Java and claimed tribute from most of the archipelago. In this period, the interests of the land-based kingdoms turned somewhat toward the sea, as a rising world interest in spices sent an arm of the Asian trade route out through new ports in East Java to the spice islands of the Moluccas.

In the 15th century began the second great wave of outside cultural influence, that of Islam. At the beginning of the century Islam found acceptance in the growing port of Malacca, which was rapidly taking over the dominant position in the Straits long held by Srivijaya; and from Malacca it spread out along the trade routes. In East Java the port towns of Majapahit embraced Islam and broke away from the central control; in the spice islands themselves and elsewhere in the archipelago coastal rulers began to adopt the Muslim title of sultan. The process continued in the 16th century: the Portuguese captured Malacca in 1511 and for a half century maintained a precarious naval and trading leadership in the islands, but a strong Islamic reaction helped, to establish powerful trading sultanates in Atjeh on the northern tip of Sumatra, and Bantam on the Straits of Sunda.

As in the case of the earliest adoption of Indian culture, it seems likely that Islam was first taken up by princes of growing states to fortify themselves for their struggle with older Hindu-Buddhist powers or newer foreign ones, and only later began to spread among the ordinary people. It is in this second process, continuing into the 20th century, that Islamic culture has been most important in Indonesian history, for the spreading and deepening of Islam has highlighted or created many fundamental tensions in Indonesian society, tensions which are still critical today. Thus it is significant that Islam, though nominally accepted by some 90 per cent of modern Indonesians, has been shallowest in Central and East Java where Indian culture was already firmly established, and has struck its deepest roots in the Outer Islands. Everywhere its spread brought it into conflict with the traditions expressed in local customary law (*adat*) and everywhere Islamic preachers formed a focus of potential or actual opposition to local traditional authorities. Finally, in sinking roots in new soil, Islam has generally been split into two rival wings, the one willing to compromise with *adat*, the other purist or modernist.

The first Dutch ships arrived in the archipelago at the end of the 16th century and by dint of hard fighting the Dutch East India Company (1602-1798) maintained itself through the 17th century as the strongest single trading power in the area. Inevitably, to secure stability for trade and protect itself from attack, it found itself exerting influence in the hinterland of Java where the inland empire of Mataram, late 16th to late 17th century, had begun to disintegrate. By mid-18th century the company succeeded Mataram as the chief land power on Java. This process ran parallel with a growing change in its economic role; increasingly from about 1700 it lost ground in open trade to the British and came to rely on sugar and coffee grown in its Javanese territories, the latter especially produced by peasants under a system of forced deliveries controlled through a quasi-hereditary administrative system centering on the traditional local aristocracy.

The disruption caused by the Napoleonic Wars in Europe, which also provided the occasion for the dissolution of the company, completed the transformation of the Dutch Indies into a territorial power centering on Java, while the revival of the forced-deliveries system in 1830, now under the Dutch state, generated huge profits for the home treasury. The increase of production and population under this system laid the groundwork for further growth in the third quarter of the 19th century as the state withdrew gradually from production and trade, and private investment grew. The opening of the Suez Canal in 1869 was a still greater impetus to investment. Expansion had a geographic aspect as well. In the mid-19th century the Netherlands Indies for practical purposes was only Java; though the Dutch exerted a casual dominance in the archipelago, dozens of small and large kingdoms maintained their independence in practice and often in theory. The Outer Islands campaigns of the late 19th and early 20th centuries, by which the Netherlands Indies assumed its modern boundaries, were stimulated mainly by economic interests and were consolidated by a tightening of administrative control and an expansion of investment.

The new Netherlands Indies which took form

in the early 20th century was, consciously and unconsciously, well adapted to dampen change. The economy was mostly based on plantation production (sugar, coffee, tea, rubber) and mineral extraction (tin and oil) for export, while industry was poorly developed. The "plural economy" of which the Netherlands Indies was a classical example, with European managers, Chinese middlemen and shopkeepers, and Indonesian clerks and laborers, was an effective insulator not least because European and Chinese interests made development of an Indonesian commercial class almost impossible. Above all, the general administrative system, based everywhere on traditional *adat* authorities—in the Outer Islands mostly indirect rule through chiefs and sultans, in Java nominally direct rule, but operating through the traditional local aristocracy—exerted a conservative influence, while in the village sphere Dutch paternalism combined the encouragement of slow progress with an effort to insulate the villager from the disruptive effects of new social and economic forces.

But the hugely expanded boundaries, production, technology, and population of the new Netherlands Indies of the early 20th century made social change inevitable and so began the third and most revolutionary wave of cultural influence, of Westernization. Nowhere was this more obvious than in the development of a new Indonesian elite, mainly secular and nationalist, in the early decades of the 20th century. This new urban elite, professional and bureaucratic rather than commercial, was a product of the modern Western education system which the Dutch had begun to develop around 1900; in Dutch schools it found the new ideas and ideals on which to base its claim to political leadership, not only against the Dutch but also against the older *adat* and Islamic elites. Growing quietly in the turbulent early years of the nationalist movement in which moderate and radical Islamic groups, Communists, and narrow-based ethnic groups all showed that they did not have the organization or ideology to lead a national awakening, this new elite emerged in the late 1920's and 1930's. The demands of its more militant wing for independence were soon muffled by Dutch repression and exile, but a much larger wing found expression through politically more moderate parties, newspapers, co-operative societies, and independent schools which testified to the increasingly solid social base of the new elite.

On March 9, 1942 the Netherlands Indies came to an end with a hasty surrender to the invading Japanese. Three and a half years of Japanese occupation brought disruption, starvation, and slave labor but politically it opened the doors to revolutionary change, for the Japanese, hoping to arouse mass support for their cause by encouraging Indonesian nationalism, deliberately destroyed all the insulators in the conservative Dutch colonial system. They gave Indonesian civil servants high responsible jobs, gave considerable power to the secular nationalist and Islamic elites while cutting deeply into the power and prestige of the *adat* leaders, they armed and trained thousands of young men on Java and Sumatra and, most important, by a ceaseless battering of propaganda, much of it nationalistic, and by promoting dozens of activist organizations, they set out to rouse the peasant masses from their political unconsciousness.

On Aug. 17, 1945, directly after the Japanese

surrendered, Sukarno and Mohammad Hatta, acting for the nationalist elite which had gained key positions under the Japanese, proclaimed the independence of the Republic of Indonesia. A constitution, a cabinet, and the choice of Sukarno as president and Hatta as vice president followed shortly. British troops, representing the Allies, began arriving in late September and their coming opened the first and most violent phase of the revolution.

The Indonesian revolution must be seen as the working out of two parallel processes, one international, the other internal. In its international aspect the revolution was a process by which the bulk of the Indonesian elite asserted and finally won its right to replace the Dutch. In principle every Republican cabinet claimed complete independence but was prepared, under pressure of Dutch military superiority and international demands for compromise, to negotiate; Dutch policy was to force or persuade mainly *adat* groups in the various regions to cooperate in the formation of member states in a Dutch-dominated federal system and to use these new states and military force to isolate and ultimately destroy or absorb the Republic. The landmarks of this international conflict were: the Linggadjati Agreement signed in November 1946 and ratified in March 1947 (cease-fire, federal system with republic as largest unit, *de facto* recognition of republic); the first Dutch "police action" July–August 1947 (West and East Java and economically important areas of Sumatra occupied); United Nations intervention leading to the Renville Agreement January 1948 (cease-fire ratification of Dutch conquests, ambiguous Dutch commitment to organize plebiscites); rapid development of Dutch-sponsored federal system in 1948; 2d Dutch "police action" December 1948 (occupation of virtually all of the republic's remaining territory, capture of most of its top civilian leaders, commencement of widespread guerrilla war by the Indonesian Army); further negotiations under United Nations auspices with international opinion and important elements within the federal member states swinging toward the republic, culminating in the Hague Agreement in November 1949 (transfer of sovereignty to a federal Indonesia with the republic as one member state, temporary retention of West New Guinea by the Dutch, Republican guarantee of Dutch investments in Indonesia).

In its internal aspect the revolution was first of all a tremendous outpouring of idealistic fervor, devoted to the development of a unitary national state based on social justice and democracy and its preservation from foreign attack. At the same time it involved a fierce struggle for power among conflicting elite groups and considerable brutality and violence, particularly against Chinese. The overriding political issue throughout the revolution was the question of whether and how far to compromise with the Dutch; the diedarh slogan of 100 per cent independence, unanswerable in terms of revolutionary ideology, was always raised by parties and factions when out of power, such as in the abortive Communist rebellion (the Madiun affair) in September 1948, and remained a permanent article of faith with most of the younger activists.

Finally the revolution effected a considerable change in the balance of power among the competing elite groups: thus *adat* groups continued to lose status and power as under the Japanese

and tended to be responsive to Dutch overtures; secular nationalists took over most important civilian posts and through various rival parties dominated the legislature and cabinets; the Islamic elite divided between a majority which joined the secular nationalists in giving priority to national independence and a militant minority unreconciled to the secularist constitution. The rise of the younger "generation of 1945," the element most active in fighting and internal reconstruction, added a fourth major elite group to the triangle. The national army was the foremost institutional form of this new elite, exercising considerable de facto power throughout the revolution.

INDORE, in-dōr', city, India, capital of Indore District in Madhya Pradesh, and formerly capital (from 1818) of the princely state of Indore. Indore State consisted of a number of non-contiguous areas, totaling 9,934 square miles, with a population (1941) of 1,513,966. The largest, most compact portion of its territory lay south of the Narbada River, overlapping the Satpura Range, while the portion containing the present district and city lay northward along the Vindhya Range and the Malwa Plateau. The state had its origin in several grants of land made in the early 18th century to the heroic peasant-born cavalry

officer, Malhar Rao Holkar, in the service of the Maratha peshwa; at Malhar's death in 1766 his domain stretched from the Deccan to the Ganges. In 1818, by the Treaty of Mandasor, it became a British protectorate and was stripped of considerable holdings, especially in Rajputana. In 1948, following Indian independence, Indore merged with other princely states into the new state of Madhya Bharat, which in turn was merged into Madhya Pradesh in 1956.

The present district of Indore, 1,563 square miles, mainly on the Malwa Plateau, is a fertile agricultural area specializing in cotton. The city of Indore is among the leading commercial and cotton-milling centers of central India. Pop. of the city (1961 provisional) 395,035.

JOSEPH E. SCHWARTZBERG.

INDRA, in'drū, a Hindu deity who is king of the pantheon in the Rig Veda, but in the epic is ruler of a heaven of sensual pleasures to which brave warriors go, and in the Puranas is a rain god of minor importance. He appears to personify the force lying in atmospheric phenomena, the wind and the storm, and has such epithets as "Son of Might" and "Lord of Power." His parentage is obscure, but he seems possibly to have been the son of Heaven and Earth, who once lived together but were driven apart when Indra drank of the marvelous Soma and swelled to gigantic and terrifying size. His great feat lay in slaying the archdemon Vritra (Vrtra), "the Covering or Restrainer," who held in confinement the Cosmic Waters (described as cows) and their son the Sun, which were needed to give moisture and light, elements necessary for the creation of the universe. Indra slew Vritra with a weapon called vajra, which was forged by Tvashtri (Tvastṛ), the artificer of the gods. This is interpreted in post-Vedic thought as the lightning, but some Western scholars have thought that in Vedic times it was understood to be a club. Vritra is interpreted in later times as the cloud covering that obscures and withholds the rain and sun. Jainism and Buddhism know Indra as a *deus ex machina*, who aids in events of cosmic importance connected with their great teachers and saints.

W. NORMAN BROWN.

INDRE, än'dr', department, France, in the west central part of the country, comprising parts of the old provinces of Berry, Orléanais, Marche, and Touraine. It has an area of 2,666 square miles and is watered by the Indre and Creuse rivers. The capital is Châteauroux; other important towns are Issoudun, Argenton, and Le Blanc. Indre is mainly agricultural, with textile, leather, and iron manufactures. Pop. (1954) 247,436.

INDRE-ET-LOIRE, än'drā-lwār', department, France, in the west central part of the country, formed out of most of the old province of Touraine and parts of Poitou and Anjou. Its area of 2,378 square miles is watered by the Loire, Indre, Cher, and Vienne rivers. Wine making is the chief industry. Tours is the capital; other towns are Chinon and Amboise. Indre-et-Loire has several famous Loire Valley châteaux. Pop. (1954) 364,706.

INDUCTANCE, in-dük'tāns, that property of an electric circuit or of two neighboring cir-

cuits which determines how much electromotive force (volts) will be induced in one of the circuits by a change of current (amperes) in either of them. Inductance is measured in henries and designated by the letter L . An electric circuit has an inductance of one henry when, if the current is changed at the rate of one ampere per second, one volt is induced in the circuit thereby. It may be measured by an inductance bridge which is similar to a Wheatstone bridge used for measuring resistance. The inductance bridge compares the unknown inductance with a known inductance standard. The inductance of a circuit may be

determined from the formula $L = \frac{X_L}{2\pi F}$ where

6.28 is 2π and F is the frequency or cycles of the circuit and X_L is its reactance in ohms. For example, the inductance L would equal 0.0595 henries in a 60 cycle circuit containing 22.45 ohms of

reactance, X_L , as $L = \frac{22.45}{6.28 \times 60} = \frac{22.45}{376.80} = 0.0595$

henries. Inductances connected in series equals their arithmetical sum. When connected in multiple, inductance $L = \frac{1}{\frac{1}{L_1} + \frac{1}{L_2} + \frac{1}{L_3}}$, etc. The term

henry was given the unit of inductance L in honor of Joseph Henry (1797-1878), whose investigations gave the world much of its present knowledge on the subject.

INDUCTION, in-dŭk'shŭn, *in logic*, is the method of reasoning employed in establishing general laws as well as propositions about individual occurrences on the basis of specific observational evidence. The intellectual operations involved in grounding Boyle's law upon actual measurements on the volume, pressure, and temperature of gases; the prediction of tomorrow's weather on the strength of meteorological data; or the determination of the circumstances of Lincoln's death on the evidence of documents and other available materials, are typical examples of inductive reasoning. In this inclusive sense of "induction," it is not antithetical to deduction, since the deductive elaboration of propositions is a feature of nearly all inquiry. Inductive and deductive inferences can nevertheless be distinguished. In valid deductive arguments, the premises logically imply or necessitate the conclusion, and constitute formally complete evidence for the latter. In inductive arguments, the premises do not necessitate the conclusion, they are not formally sufficient to establish it, but they make the conclusion probable (or warranted) to some degree. The statement that all acids turn blue litmus paper red, for example, is not logically implied by the evidential premises which express the outcome of a finite number of observations on the color changes of blue litmus in the presence of acids. The statement nevertheless possesses a measure of probability relative to those premises.

It is essential to distinguish between induction as an inclusive process of experimental investigation and discovery, and induction as that phase in this process which consists in the weighing or evaluation of the available evidence for a given conclusion. An account of induction as a concrete temporal process seeks to formulate the major steps in the pattern of inquiry: the recognition of a problem, the invention and formulation of a hypothesis as a proposed solution for it, the derivation of deductive consequences of the hy-

pothesis, the verification of some of these consequences through confronting them with data of observation or with other propositions already assumed as well-established, and the acceptance, modification, or rejection of the hypothesis in the light of the outcome of the preceding step. Such an account usually includes discussions not only of distinctively logical questions, but also of various psychological and sociological factors that may determine the direction of inquiry. Much of the literature on induction thus pays attention to the personal and social requirements for effective research, to the role of intellectual fashions and preconceptions in the development of knowledge, to techniques of observation, and to proposed ways for obtaining successful solutions to problems.

In connection with this last item, many writers on induction have sought to state general rules of experimental method, adherence to which would guarantee the discovery of the causes and effects of phenomena. The best-known of such rules are the five "Methods of Experimental Inquiry" proposed by John Stuart Mill in the 19th century. According to the Method of Agreement, if two or more instances of a phenomenon have but one circumstance in common, that circumstance is the cause (or effect) of the phenomenon. The Method of Difference states that if an instance of a phenomenon has every circumstance but one in common with an instance in which the phenomenon does not occur, that sole circumstance is the cause (or effect). The Joint Method of Agreement and Difference is a combination of the two preceding methods. According to the Method of Concomitant Variation, if variations in one phenomenon are concomitant with variations in another, the two phenomena are causally related. Finally, the Method of Residues states that if part of some phenomenon is known to be the effect of certain of its antecedents, the remainder of the phenomenon is the effect of its remaining antecedents. These canons have not, however, proved to be rules which can disclose the causal relations of things, unless the canons are supplemented with assumptions specific to a given subject of inquiry. The application of each method involves the use of some hypothesis concerning the circumstances that are relevant to the occurrence of a phenomenon under study, where the hypothesis itself cannot be extracted from any general rules of procedure, but must be supplied by the wit and the imagination of the individual investigator. With this important qualification, however, Mill's methods do formulate patterns of analysis employed in many experimental inquiries. They codify the ideal logical conditions of experimental study; they specify standards for judging the adequacy of causal imputations, even though modern experimental science is not primarily a search for "causes"; and they indicate the rationale for testing, and when necessary eliminating, hypotheses about dependencies between phenomena. But the methods are rules neither for inventing hypotheses nor for discovering such dependencies; and adherence to them does not guarantee the truth of hypotheses that have not been eliminated as erroneous.

Induction as the weighing of evidence for a given conclusion must, however, be distinguished from various other operations employed in inquiry. The problems raised by the question whether a given conclusion is adequately supported by a given body of evidence, for example, are of a

different order from those raised by the question how evidence has been or can be obtained, or by what train of thought a proposed solution to a difficulty has been reached. The distinctively logical problems of induction lead to two related groups of inquiries: to the formulation of the principles explicitly or tacitly involved in evaluating formally incomplete evidence for a stated conclusion; and to the "justification" (or validation) of these principles.

The principles studied in inductive logic are those underlying *ampliative* inference, that is, arguments where the conclusion is not logically entailed by the evidential premises. So-called "perfect" (or "summative") induction, in which a universal conclusion is based on a supposed exhaustive enumeration of its instances (that is the claim that all the planets move on elliptic orbits around the sun, on the strength of examining each of the planets *seriatim*), is a trivial instance of deduction, and plays no significant role in empirical inquiry. Moreover, the development of modern science has made highly doubtful whether there is such a thing as "intuitive induction" (traditionally regarded as the primary source of scientific knowledge), in which relations are allegedly apprehended as universally and necessarily valid by contemplating a few of their instances (for example, the alleged intuitive apprehension of the truth of the law of inertia). Ampliative inferences nevertheless differ widely in respect to the form of both their conclusions and evidential premises, and three major types are sometimes distinguished: the affirmation of a universal law or theory, on the basis of samples drawn from the population of things for which the law supposedly holds; the prediction of the composition of an unexamined sample, on the strength of the known composition of examined samples; and the imputation of some trait to an individual, on the basis of an assumed analogy between that individual and others known to possess that trait. Accordingly, the systematic presentation of the principles involved in evaluating the various arguments subsumable under these types is a difficult task. It is a task which inductive logicians have not yet completed.

It is customary to say that the conclusion in an ampliative inference is no more than "probable" on the evidence available for it. Much effort has in fact gone into the codification of the principles governing such inferences within the framework of a theory of probability. Indeed, repeated attempts have been made to apply the mathematical calculus of probability to the numerical evaluation of inductive evidence. In recent years, moreover, advances in theoretical statistics have supplied important clues to the logical structure of inductive arguments, and have contributed valuable rules for estimating the risks involved in accepting or rejecting various types of hypotheses on the strength of the statistical evidence for them. The success of these attempts to subsume inductive logic under the theory of probability is nevertheless still a moot question. There is considerable disagreement among competent students on the correct analysis of the notion of probability; and there is no unanimity among them on the relevance or applicability of many theorems in the calculus of probability to the evaluation of inductive evidence. For example, to illustrate this latter remark, according to Pierre Simon de Laplace's famous Rule of Succession, if an event (that is, sunrise every 24 hours) is known to have

occurred n times without failure, the probability of its occurrence on the next occasion is $(n+1)/(n+2)$. Although the rule is a necessary consequence of Laplace's assumptions, most contemporary students nevertheless regard some of those assumptions as inapplicable to the great majority of inductive inquiries.

Despite the unsettled state of the subject, however, there appears to be good agreement on a number of central points. It is generally recognized that the weight of the evidence for an inductive conclusion depends on the degree to which the evidence is a representative sample from the total population of relevant data for that conclusion. In weighing such evidence consideration must therefore be given to the number of independent items included in the evidence, to the variety of evidential data, to the sampling procedure adopted in gathering the evidence, and to the systematic interconnections of the stated conclusion with more inclusive assumptions for which other independent evidence is available. For example, a few careful measurements suffice to fix with high probability the approximate value of the density of a newly synthesized substance, although a large number of confirmatory observations may not establish a high probability for the conclusion that all crows are black. The rationale for this comes from the circumstance that the constancy of the density of a chemically homogeneous substance is required by a comprehensive theory of matter, for which there is a vast accumulation of independent evidence, but that a constant association of the color of plumage with anatomic or physiological structure is not entailed by any established biological theory. A very large number of observations on crows is therefore needed to make sure that the observed crows are a representative sample from the crow population. Space forbids, however, a fuller discussion of the details of inductive logic.

The second question to which the analysis of inductive inference leads is that of "justifying" them. Many writers have sought to find a deductive justification, which would establish the validity of inductive arguments by demonstrating that, granted the evidential premises, the conclusion either must be true or be true with some specified probability. To achieve this end, a comprehensive assumption is generally introduced as an additional premise for all inductive arguments, so as to convert the latter into deductive ones. A premise of this sort frequently proposed is the Principle of the Uniformity of Nature, which asserts that "what happens once, will, under a sufficient degree of similarity of circumstances, happen again." But quite apart from difficulties of detail, there is the fundamental objection that a deductive justification of induction postulates an irrelevant standard of validity for the latter. Many students have therefore abandoned the quest for a deductive justification as radically mistaken. Some of these have in fact taken the position that in no sense whatever can inductive arguments be justified, since the rules underlying such arguments are merely tacit definitions of what constitutes "reasonable" evidence. This view, however, is not easily compatible with the generally admitted fact that some inductive procedures are more effective than are others in achieving the ends of inquiry. Another group of students, finally, also regard attempts at a *wholesale* justification of induction as misplaced effort. These students seek, nevertheless, to assess the relative worth of various

specific forms of inductive inference, in terms of the actual successes in the past of those arguments in yielding reliable conclusions to determinate problems of inquiry.

ERNEST NAGEL,

Professor of Philosophy, Columbia University.

INDUCTION, in physical science, the process by which an object is electrified, magnetized or given an induced voltage by exposure to a field, but without direct contact. The principle of electromagnetic induction was discovered by Michael Faraday (1791–1867) in 1831 and has proved the greatest of all discoveries in electrical science. It is the basis for the generation of commercial electricity as used throughout the world. Faraday had spent nearly 11 years trying to find a more satisfactory source of electricity than that produced by crude inefficient batteries. Faraday's discovery was that electricity may be generated by moving an electrical conductor in a magnetic field. This is the principle upon which the dynamo or generator is founded. (See GENERATORS, ELECTRIC; ELECTROMAGNETISM.) It is known as electromagnetic induction. Electromagnets are used almost entirely to supply the magnetic flux for the generation of electricity. Permanent magnets are only used on small generators, often referred to as magnetos. Magnetic induction covers the attraction or repulsion of magnetic materials such as iron and steel by either a permanent or by an electromagnet. The term induction applies here as attraction or repulsion and takes place through space as no contact is required.

Electrostatic or Statical Induction (also called **Electric Induction**).—An object is charged electrically by bringing it into an electrical field of an already charged object. The capacitor operates on the principle of electrostatic induction. It is due to the principle of electrostatic induction that an alternating current will flow through a capacitor. A direct current will cause electrostatic induction in a capacitor only at the time of connecting the capacitor to the circuit. This is called charging the capacitor. This charge will remain in the capacitor until the capacitor is discharged or lost by leakage. A direct current will not pass through the insulation of a capacitor. It should be noted that an alternating current passes or flows through the capacitor only by induction through the insulating medium of the capacitor. The alternating current has movement by varying in intensity and direction while direct current remains constant except at the instant its circuit is closed or opened.

Mutual Induction.—The production of a voltage, electromotive force, in one electric circuit by varying the current in an adjacent circuit is mutual induction. The magnetic flux or field produced by an electric current flowing through a conductor or coil always spreads out symmetrically and more or less uniformly to form closed magnetic paths. If any of this flux or magnetic lines pass directly through other conductors or a second coil the flux will be mutual to both coils. By mutual induction an electromotive force, volt-

age, will be produced in the other conductors or coil, as the case may be, provided there is movement of the flux. Mutual induction is the principle upon which automatic control devices, induction motors and transformers operate. (See TRANSFORMER.) It should be noted that an electrical contact between conductors or coils is not necessary to establish mutual induction.

Self-Induction.—Briefly stated, self-induction is the production of a voltage in a circuit by varying current in that same circuit. If an electric current passes through a conductor it sets up a magnetic field around the conductor. If this current, amperes, changes in value, the magnetic field, flux, produced by the current will also change. This change in flux will produce a voltage within the conductor and this voltage is the voltage of self-induction. (The subject of self-induction is closely related to that of inductance and should be jointly considered. See INDUCTANCE.) The voltage created by self-induction is opposite in direction to the original voltage applied to the conductor. When a circuit is supplied with direct current self-induction is present only at the moment when the circuit is closed. After the circuit is closed and the current is steady there is no movement of the magnetic field or flux. Self-induction is present in any circuit containing magnetic equipment when supplied by an alternating current. Such circuits are said to be inductive. Such currents are varying constantly and thus create a changing flux which in turn creates an opposing voltage, the voltage of self-induction.

E. S. LINCOLN.

INDUCTION, Mathematical, is a process of proof applying most directly to theorems about the collection of all *natural numbers*:

0, 1, 2, 3, . . .

When it is required to prove a general proposition:

For every natural number n , $P(n)$,

the use of mathematical induction consists in proving instead both the general proposition,

(1) For every natural number n ,
if $P(n)$, then $P(n+1)$.

and the singular proposition,

(2) $P(0)$.

The adequacy of such proof rests intuitively upon the fact that each of the propositions:

If $P(0)$ then $P(1)$,
(3) If $P(1)$ then $P(2)$,
If $P(2)$ then $P(3)$,
etc.,

is a consequence of the general proposition (1) and that the propositions:

(4) $P(1)$, $P(2)$, $P(3)$, etc.

follow successively, one by one, from propositions (3) and proposition (2). In brief, the general proposition warrants inference from *each* special case to the *next*, while the singular proposition states the first case outright. Assurance is thus obtained that *every* special case can be proved.

As an example, proof by mathematical induction that:

For every natural number n ,

$$1 + 2 + 4 + \dots + 2^n = 2^{n+1} - 1,$$

consists in showing:

(1') For every natural number n , if

$$(a) 1 + 2 + 4 + \dots + 2^n = 2^{n+1} - 1$$

then

$$(b) 1 + 2 + 4 + \dots + 2^n + 2^{n+1} = 2^{n+2} - 1;$$

$$(2') 1 = 2^1 - 1.$$

Proof of (1') is made by starting with equation (a), adding 2^{n+1} to both sides, and obtaining thereby equation (b), since $2^{n+1} - 1 + 2^{n+1} = 2^{n+2} - 1$.

This form of argument is also known as *proof by recursion*, *complete induction*, *finite induction*, and—in German writings—*proof from n to $n+1$* . These names are likewise given to various related but more complex forms of argument.¹

Principle of Mathematical Induction.—Consider any property of natural numbers and suppose that:

- (1) If any natural number n has the property then its *successor* $n+1$ also has the property (the property is *preserved under succession*),
- (2) The number 0 has the property.

Then:

Every natural number has that property.

This is the *principle of mathematical induction*. It ascribes to the system of natural numbers a special structure in terms of the notion of successor, by virtue of which structure proof by mathematical induction—and definition by induction (cf. below)—is sound and adequate.

In the axiomatic treatment of arithmetic by Giuseppe Peano (1858–1932)²—in which *natural number*, *zero*, and *successor* are primitive terms—mathematical induction is secured by taking this principle as one of the axioms. In the Gottlob Frege-Bertrand Russell derivation of arithmetic from logic³—in which *cardinal number*, *zero*, and *successor* are all defined in terms of logical notions—the natural numbers are defined to be the *inductive* cardinal numbers, that is the common part of all collections of cardinal numbers which (1) whenever they contain any cardinal number also contain its successor (collections *closed under succession*) and (2) contain the number 0. In this context the principle of induction can be *proved* of the natural numbers by virtue of their definition. In an axiomatic treatment of the system of *real numbers*,³ the collection of natural numbers can again be distinguished by essentially this same definition, and the principle of induction proved of the natural numbers as defined.

The intuitive justification of the principle may be put in these terms: The system of natural numbers is generated in its normal order of magnitude from the number *zero* solely by the process of *succession* (as in the act of counting). The premises of the principle insure that the property

in question belongs to zero and that, as each number is generated, it must belong to that number since preserved under succession. Hence, there being no other natural numbers than those generated in succession, the property belongs to every natural number.

It is apparent from the foregoing that the appellation, *mathematical induction*, is a misnomer. Mathematical induction is a thoroughly deductive process—in some contexts the principle is itself demonstrable—remote from any conception of induction found in the empirical sciences. Nor does it represent an inference from particular to general, but rather inference of one generality from another (and a particular).

Well-Ordering Principle.—The structure of the system of natural numbers is such that it can be said of any two numbers which is the smaller. The system is thus an *ordered* system in which 0 is the least element and, for any number n , n is less than $n+1$. In terms of this order relation, the basis of mathematical induction can be put in perhaps its most compelling form:

In every (non-empty) collection of natural numbers there is a least number. By virtue of this property, the collection of all natural numbers is said to be *well-ordered*. The principle of induction follows readily from the well-ordering: Let P be a property satisfying the principle of induction; if there are any numbers for which the property P fails, let $n+1$ be the least such number ($n+1$ because 0 is *not* a number for which P fails). Then the number n (less than $n+1$) has the property P , hence so does $n+1$, which is a contradiction. Hence there are no numbers for which the property fails.

A proof by mathematical induction may also take the form of proving that:

For every natural number n , if the property P holds of every natural number less than n then the property P holds of n itself.

(This includes the case that P holds of 0, since there are no natural numbers less than 0.) The soundness of this procedure follows immediately from the fact that the natural numbers are well-ordered. Indeed this procedure, although in the case of the natural numbers it is equivalent to process of inference originally stated, is in other contexts much more powerful. It applies, under the name of the principle of *transfinite induction*, to proofs in the theory of *transfinite numbers* and to proofs about the elements of any collection which can be well-ordered. It has been a matter of controversy among mathematicians whether every collection can be well-ordered (the *well-ordering principle*), that is, whether this strong kind of induction can be applied to arguments about any collection whatsoever; the predominant opinion is that it can.

Definition by Induction.—The sense of the operation of *multiplication* (of natural numbers) is expressible by the pair of equations:

$$a \times (n+1) = (a \times n) + a; a \times 0 = 0.$$

Using the notation n' (instead of $n+1$) for the successor of n , the equations take the form:

$$a \times n' = (a \times n) + a; a \times 0 = 0.$$

Addition may be similarly defined by:

$$a + n' = (a + n); a + 0 = a.$$

These are examples of *definition by induction* or *recursive definition*. If the numerals, 0, 1, 2, 3,

¹ A number of interesting illustrations of proof by mathematical induction will be found in Courant, R., and Robbins, H., *What is Mathematics?* (New York 1941).

² Russell, B., *Introduction to Mathematical Philosophy* (London 1919).

³ Graves, L. M., *Theory of Functions of Real Variables* (New York 1946).

etc., be understood as abbreviations of the signs, $0, 0', 0'',$ etc., then these definitions accomplish the explanation, for example, of 2×2 , stepwise in terms of 0 and successor: $2 \times 2 = (2 \times 1) + 2 = ((2 \times 0) + 2) + 2 = (0 + 2) + 2 = (0 + 2)' = (0 + 2)'' = (0 + 1)''' = 0''' = 4$.

The technical notion of *general recursive function*⁴, of which the above are two special cases, is defined as follows: A finite set, ε , of equations determines a general recursive function, $f(x_1, x_2, \dots, x_n)$, if for every set, $X_1, X_2, \dots, X_n$, of numerals there is exactly one numeral Y such that the equation, $f(X_1, X_2, \dots, X_n) = Y$, is obtainable as the last of a finite sequence of equations, each of which is either one of the equations of the set ε or itself obtained from earlier equations of the sequence by:

- (R1) Passage from an equation, $A = B$, containing a *variable*, say y , to the equation which results from $A = B$ by substituting a numeral, Y , for y throughout;
- (R2) Passage from an equation, $A = B$, containing *no variables* and an equation of the form $g(X_1, X_2, \dots, X_k) = Y$, where $X_1, X_2, \dots, X_k, Y$, are numerals, to the equation resulting from $A = B$ upon replacing one or more occurrences of $g(X_1, X_2, \dots, X_k)$ in B by Y .

In the case of addition, an appropriate set ε is:

- (1) $S(a, n') = (S(a, n))'$
- (2) $S(a, 0) = a$.

The finite sequence of equations to show that $1 + 2 = 3$ (i.e., that $0' + 0'' = 0'''$) continues:

- (3) $S(0', 0) = 0'$ by (R1)
- (4) $S(0', 0') = (S(0', 0))'$ by (R1)
- (5) $S(0', 0'') = (S(0', 0'))'$ by (R1)
- (6) $S(0', 0''') = ((S(0', 0''))')$ by (R2)
- (7) $S(0', 0''') = ((0'))' = 3$ by (R2)

To show that this or any set, ε , of equations does in fact define a general recursive function is of course a matter for proof by mathematical induction. The question is whether such a set, ε , permits computation for *all* natural numbers as arguments, as this set has been seen to do for 1 and 2.

The distinguishing feature of general recursive functions, which gives them their importance in logic and foundations of mathematics, is that the value of such a function for any particular arguments can be explicitly computed in a finite number of steps. They are therefore capable of explicating the notion of *effective process* or *constructive method*.

In symbolic logic it is required that there be an effective criterion to recognize whether a given sequence of symbols is a sentence or whether a given sequence of sentences is a proof. By associating numbers with sequences and symbols an effective criterion to recognize a sentence may be identified with a general recursive function whose value is 0 for such numbers as are associated with sentences and is 1 for all other numbers. Demands of the *mathematical intuitionists* that all mathematical proof be by means of constructive methods can be made precise by identifying such methods as those for which an associated general recursive function can be provided.

Several other, independently proposed, expli-

cations of the notion of effective process⁵ have been proved equivalent to general recursiveness, which suggests that all these equivalent explanations are fundamentally correct. The identification of the vague notion of effective process with the precise notion of general recursiveness has for the first time allowed the proof that for certain problems no effective process of solution exists; e.g., in symbolic logic, while effective criteria exist whether a sequence of sentences is a proof no such criterion exists beyond an elementary level for whether a given sentence is a theorem.

Mathematics and Logic.—At a time when the syllogism was accounted the only significant tool of logical demonstration, mathematical induction appeared to transcend the bounds of logic by requiring an infinite sequence of hypothetical syllogisms in its employment. It was thought in consequence to be the distinctive mark of mathematical reasoning.⁵

The development of logic to the level which permitted the Frege-Russell reduction of mathematics to logic issued, on the one hand, in a definition of natural number, of which definition the principle of mathematical induction is a purely logical consequence, and on the other, in the systematic use of mathematical induction in the investigation of questions which would appear to be clearly within the province of logic.⁴ The use of mathematical induction will thus no longer serve to distinguish these two disciplines, if they are two.¹

Assistant Professor of Mathematics, The College
of the University of Chicago.

INDUCTION BALANCE, an instrument for measuring the electrical conductivity of metals which operates upon the basis of counterbalancing two induced electrical currents. It was originated by Heinrich Wilhelm Dove in 1841 and improved as a practical device by David Edward Hughes in 1879. Essentially it consists of two sets of induction coils. A current of electricity from a battery passes through both of the primary circuits of the two induction coils, and, in addition, through a circuit breaker. A current is induced and flows in the secondary coils when that in the primaries is rapidly made and broken. The two primary coils are connected to the battery in such a manner that the current flows through them in opposite directions. Thus the induced currents traversing the two secondary coils also flow in opposite directions. If, therefore, a telephone is inserted in the circuit of the secondary coils the buzz resulting from the make and break of the primary current will be heard in the telephone so long, but only so long, as the two currents are unequal in potential; if the two currents are equal they neutralize one another and no sound is audible. Suppose that this latter condition prevails. If, now, a piece of metal is placed near *one* of the pairs of coils the primary circuit of this coil will act upon the metal giving rise to induced currents within the metal and this affects the induced (secondary) current of this one coil. As a result the two secondary currents are no longer equal and a sound in the telephone notifies the experimenter of this fact. In such a manner a piece of metal, a bullet for example, may be detected in the human body without recourse to

⁴ Kleene, S. C., *Introduction to Metamathematics* (New York 1952).

⁵ Poincaré, H., *Science and Method* (New York 1952; original French ed. 1908).

X-ray photography. An induction balance for this purpose was designed by Alexander Graham Bell and later was employed in an attempt to locate the bullet which caused the death of President Garfield in 1881.

Diversity in the intensity of the induced currents, and therefore of the sound emitted by the telephone, depends not only upon the mass of the interfering metal and its position in relation to the two sets of induction coils, but, in addition, upon the particular electrical conductance of the metal in question. It follows that the induction balance may serve to measure the specific conductance of a given metal; employed in this manner the instrument is known as an induction bridge. The induction balance furthermore may be used to measure the sense of hearing, the perception of sound being determined while varying the positions of the coils; thus used the instrument is known as an audiometer.

CARROLL W. GRIFFIN,
Professor of Chemistry, Vassar College.

INDUCTION COIL, a device used for changing a low-voltage direct current into a high-voltage alternating current. Its general construction consists of a round bundle of fine iron wires, the core, wound with a few turns and layers of comparatively large copper conductor, primary, over which are wound many turns and layers of fine copper conductor, or wire, secondary, as shown in the illustration. The primary winding is connected in series with a vibrating contact shown at the right in Fig. 1. This vibrating contact actuated by magnetism in the magnetized core opens and closes the primary current and induces by mutual induction a current in the

Fig. 1. Diagram of an induction coil.

secondary winding or coil. Sparking at the contacts is reduced by a condenser or capacitor connected across the contacts (as shown in Fig. 1). When the contacts open the primary circuit the winding quickly discharges its current into the capacitor. This in turn causes a quick collapse of the magnetic field produced by the primary and causes a high voltage to be induced in the secondary circuit. Induction coils have been built for producing sparks ranging from a fraction of an inch up to several feet in length. Induction coils were in common use before the alternating current transformer took over the field of producing high voltages. However, the induction coil is used for providing the ignition spark necessary

to operate the engine in the automobile. The induction coil receives direct current from the storage battery in the automobile and steps it up to a high voltage. This high voltage jumps the small gap in the spark plugs and ignites the gasoline mixture in the engine cylinders. The induction coil without its vibrator is also used in telephone instruments.

INDUCTION COMPASS, an instrument also known as earth inductor compass. Its indications depend on the current generated in a coil of wire revolving in the magnetic field of the earth.

INDUCTION FURNACES. See FURNACE—4. *Electric Furnaces.*

INDUCTION GENERATOR. If an induction motor is operated by mechanical means at a speed higher than its rate, synchronous speed, it will act as a generator. It cannot, however, act alone as a generator and can only generate electricity when connected to an electrical system also supplied with power from regular or standard synchronous generators. This is due to the fact that an induction generator must receive its field excitation current from the system to which it is connected. In order to produce such an excitation current, a leading current must be taken from an induction generator. This means a capacitive load from static condensers (capacitors) or synchronous machines connected to the system. The speed of the induction generator does not determine the frequency (cycles) of the system to which it is connected. Such frequency must be provided by the synchronous generators connected to the same system. (See GENERATORS, ELECTRIC.) In certain applications of electric locomotive operation, by induction motors, their action as a generator by overspeeding is utilized as a braking or speed-reduction means for the locomotive.

INDUCTION HEATING. See FURNACE—4. *Electric Furnaces.*

INDUCTION INSTRUMENT, an instrument or meter, as it is usually called, which depends for its operation upon the induction between a magnetic flux (or fluxes) set up by one or more currents in fixed winding or coils, and electric currents set up by electromagnetic induction in conducting parts of its moving system. A good example of an induction meter is found in the so-called watt-hour meter found in practically all homes using alternating current. It is the meter used for determining how much electricity has been used in the home and provides the basis for the cost of electricity used.

INDUCTION MOTOR. See ELECTRIC MOTORS.—*Alternating Current Motors* (Induction Motors).

INDUCTION REGULATOR, a device used to regulate the voltage of a system independent of the generator supplying the system voltage and current. A good example of its use is in the supply of electricity in residential districts. Here the induction regulator is used to boost or increase the voltage to homes when the load is heavy and to decrease the voltage when the loads are light. In other words its object is to main-

tain a constant voltage on a distribution system or feeder regardless of the load. Induction regulators work on the principle of the transformer, having a fixed primary coil and a movable secondary coil. The movable secondary coil is designed to either add or subtract from the system voltage anywhere from 0 to 15 per cent of the normal voltage supplied to the regulator. A lineman would call such action "boosting" or "bucking" the line voltage.

INDUCTIVE INTERFERENCE. When an alternating current power line runs parallel to a telephone line it will, under certain conditions, interfere with telephone conversations in the telephone lines. In the early days of the alternating current lighting systems it put many telephone systems out of use. This was due to the induction of currents from the power system inducing interfering currents into the telephone system. (See **INDUCTION**.) Such objectionable interference has been eliminated by transposing wires in both systems so as to equalize the currents in all telephone wires. The transposing of wires means exchange of location or the crossing from one insulator to an adjacent insulator on a telephone pole cross arm. Running wires in cables with metal sheaths, or coverings, which are grounded, has entirely removed inductive interference.

INDUCTIVE LOAD, a load on an electric circuit containing magnetic or inductive equipment. The cause of an inductive load is inductance in the circuit. An inductive load is sometimes called a lagging load, as the current in the circuit lags behind the voltage impressed upon the circuit. (See **ALTERNATING CURRENT**.)

INDUCTOR-TYPE GENERATOR is an alternating current generator in which the armature and field are both stationary. The stationary field magnetizes a rotating inductor which in turn causes magnetism to pass through the stationary armature conductors or coils. Such inductor alternations were used in the early development of alternating current systems. This type of generator is now used for obtaining high frequency (3,000 to 10,000 cycles) currents for use in induction heating furnaces.

INDULGENCE, ĭn-dŭl'jĕns (Latin, *indulgentia*, gentleness; hence concession and pardon), is defined by the Roman Catholic Church as "the remission before God of the temporal punishment due to sin after its guilt has been forgiven, which ecclesiastical authority grants from the treasury of the church, in behalf of the living after the manner of an absolution, and in behalf of the dead after the manner of an intercession." (*Code of Canon Law*, Can. 911.) Certain terms in this definition and certain related doctrines must be explained for an understanding of indulgences.

An actual sin is any willful thought, desire, word, action, or omission forbidden by the law of God. A grievous, or mortal, sin deprives the soul of sanctifying grace, and consequently of its right to everlasting happiness in heaven, and takes away the supernatural merit of its good actions. Venial sin does not destroy sanctifying grace. In addition to guilt for having offended God, the sinner incurs punishment for his misdeed. Eternal punishment is the everlasting loss brought upon himself by one who has committed a mortal sin

and dies unrepentant. Temporal punishment, or that limited in duration, is due for venial sins and for mortal sins that have been pardoned but for which further satisfaction must be made. The doctrine of indulgences refers neither to the pardon of mortal or venial sin nor to the remission of eternal punishment. It is concerned only with the temporal punishment still due either for venial sin or for mortal sin that has been repented for and pardoned by God. The reality of such punishment is seen from Sacred Scripture (Deuteronomy 32:51-5, 2; II Kings 12:13-19; Matthew 3:8; Luke 3:3), the tradition of the church, and natural reason. In the primitive church severe canonical penances were imposed on those guilty of serious sin. Since God's justice requires reparation for wrongs done, the repentant sinner who has failed to pay his debt of temporal punishment in this life will be required to do so after death in purgatory (q.v.).

The church, the Mystical Body of Christ, is made up of the visible church with its members here on earth (the church militant), the souls in purgatory (the church suffering), and the saints in heaven (the church triumphant). As in a living organism, one member can aid another who needs help. Within the church militant, members help one another by prayers and good works. They invoke the intercession of the saints in heaven, who in turn help them. They help the suffering souls in purgatory by prayers and by performing good works in their behalf. The treasury of the church is made up of the infinite merits of Jesus Christ and the superabundant merits of the Blessed Virgin Mary and the saints. It draws upon this inexhaustible storehouse and enables the faithful on earth to lessen their own debt of temporal punishment and also that of the souls in purgatory. An indulgence is therefore a transfer of some of the merits of Christ and the saints from this spiritual treasury to the faithful. As such, it is an exercise of "the power of the keys," granted by Christ when He said: "Thou art Peter, and upon this rock I shall build my church, . . . And I will give thee the keys of the kingdom of heaven; and whatever thou shalt bind upon earth shall be bound in heaven, and whatever thou shalt loose upon earth shall be loosed in heaven." (Matthew 16:19.) As successor of St. Peter, the pope has full power to grant indulgences, and those that he grants to the universal church can be gained by all Roman Catholics.

Indulgences are of two main kinds, partial and plenary. Since a partial indulgence is the remission of some of the temporal punishment due for sin, it is expressed in terms of time. Thus a partial indulgence may be for "100 days," "one year," or some other stated time. Such terms are relative and are not to be understood in a literal sense, as if the indulgence is good only for a certain period or remits exactly that period in purgatory. The use of these terms derives from the canonical penances of the early church. Thus a partial indulgence of 50 days signifies that it is the equivalent of a similar period of penance in the early church. A plenary indulgence remits all the temporal punishment still due for a person's sins. Although a person cannot affirm absolutely that he has fulfilled all the requirements for a plenary indulgence, yet "a plenary indulgence is understood to be so granted that if one should be unable to gain it fully, he will nevertheless gain it partially, in keeping with the disposition that he has." (Canon 926.)

That a person may be capable of gaining an indulgence, he must be baptized, not excommunicated from the church, in the state of sanctifying grace, at least when he completes the prescribed good works, and the subject of the grantor of the indulgence. He must also have at least a general intention of acquiring the indulgence. The prescribed works must be fulfilled at the appointed time and in an appropriate manner. To gain a plenary indulgence, a person must be completely free from all his sins without exception, including his venial sins. No one who has gained an indulgence can apply it to another person who is still living, but all indulgences granted by the supreme pontiff, unless the contrary is evident, are applicable to the souls in purgatory, who are thus helped in a most efficacious manner. As stated in their definition, indulgences are applicable to the faithful departed "by way of intercession," that is, the church petitions God to accept these works of satisfaction and to shorten the temporal punishment in purgatory as He sees fit.

Indulgences are frequently attached to prayers, religious exercises, visits to churches, pilgrimages, and similar good works. During the Middle Ages they were often attached to such works of charity as contributions to building hospitals, bridges, and churches, and in this way they had great social influence.

INDULGENCE, DECLARATION OF.

See DECLARATION OF INDULGENCE.

INDUS, in'dūs, an important river of southwestern Asia. Rising in the lofty tableland of Tibet not far from the source of that other major Indian river, the Brahmaputra, it flows for some distance in a northwesterly direction at an elevation of nearly three miles. Crossing the towering Ladakh ranges, it traverses matchless scenery within 60 miles of K², the loftiest summit of the Karakoram Range, to swirl about the base of Nanga Parbat, the westernmost bastion of the Himalayas. This peak, rising nearly 23,000 feet above the current, presents the greatest contrast in neighboring elevations to be found anywhere. Flowing through Baltistan and Kashmir and swollen by the meltings of giant glaciers, the Indus bends to the southwest to be joined by the more extensive rivers of the Punjab—the Jhelum, the Chenab, the Ravi, and the Sutlej. Skirting the Thar or Indian Desert, it loses much volume to scorching winds and still more to the irrigation canals and ditches which nourish that arid region. In its course of 1,976 miles, it drains an area of 372,000 square miles to empty by several mouths through a delta fronting for 130 miles upon the Arabian Sea.

The Indus is turbulent in flood time. At Attock it has risen more than 80 feet so that the Kabul tributary reversed its current to flow backward into Afghanistan. While volume varies, the average flow at Sukkur as recorded by the Indus

River Commission during a period of 50 years is 155,000 cubic feet per second. Enormous quantities of silt are swept away to expand the ever growing delta. During the three-month period of maximum flow, this silt totals six billion cubic feet.

Indus is derived from the Sanskrit Sindhu, meaning river. From the same root comes India and the Indian Ocean. Further ramifications of nomenclature embrace the East and West Indies and the Indians of the Western Hemisphere, so that the name of no other river has been so variously repeated upon the maps of the world.

The Indus was well known to the ancients. It was sketched with tolerable accuracy by Eratosthenes and Ptolemy, although its source remained hidden beyond the mountains. Alexander the Great sailed down its channel to the sea. Aristobolus wrote that a thousand Indian cities had been abandoned because the Indus had shifted its course. Within the past two centuries it has eroded its present bed through limestone ridges three hundred miles from the sea. The seven mouths enumerated by Ptolemy have also changed through the centuries as former channels were choked and new ones opened up.

Like the Nile and the Euphrates, the Indus was the cradle of prehistoric cultures. The ruins of Mohenjo-Daro and Harappa, recently unearthed in its valley, were among the earliest of city states. Here, so Sir John Hubert Marshall (1876–) claims, living conditions excelled those of contemporary Egypt and Babylon.

Though traversing some of the most rugged country in the world, the upper Indus Valley has always been the "gateway to India." Through its precipitous passes came the conquering Aryans and the exploring armies of Alexander the Great, to be followed by ruthless Moslem raiders, by Genghis Khan, Tamerlane (Timur), and the great Moguls.

With the partition of India into two sovereign states, the valley of the Indus is once more the scene of strife and disagreement. The status of Kashmir is still undetermined. While the main stream of the Indus lies within Pakistan, the boundary between that country and India crosses several important tributaries. Hence, disputes persist over the sharing of irrigation waters so vitally needed in an agricultural area and the development of hydroelectric power in a region almost destitute of coal.

INDUSTRIAL ACCIDENTS. See ACCIDENTS, CAUSES AND PREVENTION OF—*Occupational Accidents*.

INDUSTRIAL ALCOHOL. See DENATURED ALCOHOL.

INDUSTRIAL ARBITRATION. See ARBITRATION, INDUSTRIAL.

INDUSTRIAL ARCHITECTURE is that branch of building that houses the production of man-made commodities. As such it includes power plants, mills, and factories of all types. By extension, it may comprise also those edifices provided for the convenience of the industrial workers, offices for the administrative staff, warehouses for the storage of finished goods or raw materials, and such others as are corollary to the industrial process. So long as production remained in the

handicraft stage, and was consequently carried on in the home of the worker, no architecture of industry as such was possible. However, with the advent of power to run machinery, the industry of the home began to give way to that of the mill and factory, and industrial architecture was born. Its needs were and are utilitarian. Economic pressure insured that designing for visual effect would be subordinate to designing for use. Therefore, the influence of historic styles in architecture could play only a minor role. The absurdity of clothing a power plant with details derived from a Greek temple, or a locomotive works as a Gothic church, was too costly to be tolerated, though the shape of the tower from the Palazzo Pubblico, Siena, of the late 13th century, was draped around a certain 19th century factory chimney in London. It does not follow that industrial buildings need to be ugly, but that their beauty must issue from a frank acceptance of their purpose unclouded by nostalgic references to the past.

The first requisite for a successful industrial building is the selection and development of the site. The choice of the site will be conditioned by the product to be manufactured. Transportation for the necessary raw materials and for the finished product will suggest proximity to water, rail, road, or, in the 20th century, air routes, depending on the nature of the finished article. The particular manufacturing process may prescribe a location adjacent to a source of power. Thus many of the early mills were built where rivers could be dammed for water power. Hydroelectric plants are necessarily so placed today. The availability of such public services as electricity, gas, sewage, and water supply are prerequisite; without them, their cost must be added to the price of the product. Where large numbers of workers are expected, some means of public transportation or of roads and adequate parking facilities to bring them to and from their work forms part of the problem unless housing is to be provided for them close to the factory. The nature of the soil conditions as they affect the cost of the buildings, of normal atmospheric conditions that may influence some manufacturing processes, of local building laws are other factors. In addition, the relation of the proposed enterprise to the community must be considered. To place a slaughter house or a boiler plant in the midst of a high-class residential area would be destructive to that area no matter how desirable the site might be in other respects.

The nature of the particular manufacturing process involved will dictate the arrangement of the building. The designer must be so conversant with this process that his building will promote an uninterrupted flow from the reception of the raw material through perhaps many machines in orderly sequence to the emergence of the finished product. He must provide space enough for adequate and safe operation of the machinery but not so much as to involve waste of time. He must provide such electrical, gas, water, fire-fighting, heating and ventilating, cleaning, and internal communication facilities as are appropriate. The materials selected for the building stem from its nature. Floors that must withstand the wear of interior trucking must not only be heavier than normal in construction but surfaced accordingly. They may need to be resistant to chemical action and should be easy to keep clean. The latter may be especially significant where the product involves close tolerances. Finally, the

welfare and comfort of the workers are important. This factor was not always recognized in the older mill designs, but 20th century industry realizes that, in addition to humanitarian considerations, the physical and mental well being of the worker affects his efficiency. Hence lighting, whether artificial or natural, must be abundant but without glare. Sound-absorbent walls and ceilings may reduce excessive noise. Cleanliness and effective ventilation help to preserve the health of the operatives. Industry has even experimented with the psychological effects of interior colors and finishes. In addition, it has provided, at times, first aid and other medical offices, cafeterias or dining rooms, lounges, dressing, locker, and shower rooms for its staff, athletic facilities, and even kindergartens and supervised playgrounds for the children of its employees while the parents are at work.

In view of the utilitarian nature of industrial buildings, it is not surprising that the potentialities of new materials and methods of construction were more eagerly accepted in them than in traditional types of building. Before iron became available for construction at low cost, and for many years thereafter, slow burning or mill construction was common. Its purpose was to minimize losses by fire. Brick walls or a frame of timber posts supported heavy wooden beams. These carried thick plank floors and similarly solid roof construction. Although the material was inflammable, the absence of enclosed spaces, such as exist in ordinary wood construction, made it difficult for fire to spread, and since all surfaces were exposed, if fire should start, it could be controlled rapidly. The strength of iron invited its use for industrial designs, and as early as 1780, cast iron columns began to replace wooden posts in English cotton mills. Matthew Boulton and James Watt took the next step in 1801 in the Philipp and Lee cotton mill at Salford, Manchester, England, where they combined iron floor beams with cast iron columns. Brick arches spanned the intervals between beams to support the floor. Then in 1848 in New York, James Bogardus built a five-story factory whose outer walls were made of precast iron sections. Jules Saulnier in 1871-1872 devised the first metal skeleton, fully braced, whose brick walls merely filled the interstices in the frame. This step, so prophetic for later skyscraper construction, was made in the Menier Chocolate Works at Noisiel-sur-Marne, a building erected over the bed of the river whose current provided the necessary power. Meanwhile, builders were beginning to experiment with concrete. In 1824, Joseph Aspdin patented Portland cement. Then in 1854, W. B. Wilkinson in England patented (the patent was sealed in 1855) a system of constructing floor slabs, girders, and beams with iron rods or wires embedded in the concrete to provide tensile strength. Wilkinson specifically recommended his method for warehouses. This was followed by a treatise on concrete, published in 1761 by François Coignet, who is said to have built a concrete roof slab at St. Denis as early as 1852. The latter half of the 19th century saw many patents issued for various forms and applications of concrete, such as those of Joseph F. Monier (1867), and Coignet (1869).

The advantages that may accrue from these developments were not available when the first factories were built or even for the earliest extant mills. The oldest cotton mill still standing in the United States is the Slater Mill, Pawtucket, R. I.

(1793). Though larger than contemporary private houses, its clapboarded walls, double-hung window sash, and severe cornice at the eaves of a pitched roof recall the domestic architecture of its day. However, all decorative detail was suppressed save for the belfry, and even that was necessary to summon the workers to their posts. Early in the 19th century, rubble masonry began to replace wood for the outer walls. As it did so, the scale became larger and less domestic. By the middle of the 19th century, brick walls were thickened between the windows to become piers and to express the mill construction within, as in the White Rock Manufacturing Company, Westerly, R. I. (1849). The range of the Amoskeag cotton mills along the river in Manchester, N. H., is impressive. By 1870, the date of the Lippitt woolen mill, Woonsocket, R. I., brick piers supported granite lintels of wide span to approximate a skeleton construction; windows were larger and although the mansard roof smacked of the Vic-

form an intelligent expression of concrete. Vast expanses of glass flood the interior with light. The great hall interior is high, not for architectural effect though it has that too, but to permit of overhead traveling cranes for the placement and repair of the machines. The same consideration operates in such hydroelectric power plants as that at the Hoover Dam. Modern installations, especially those publicly owned, provide for visitors in such a manner that they will not interfere with the operation of the plant. Few buildings better suggest the titanic forces generated within than the concrete and steel masses of the Cahokia Power Station, East St. Louis (c.1925) by Mauraan, Russell, and Crowell, where four pairs of ponderous smokestacks create a powerful rhythm. Recently forced draft has replaced stacks, in part because of their danger to air traffic. The influence of the assembly line is apparent in the five story Fiat automobile factory, Turin, Italy, designed by Matté Trucco. Spiral ramps at either

Lady Esther, Ltd. office and factory erected in Chicago 1937-38; designed by Albert Kahn Associated Architects and Engineers.

torian, it created a spacious and well lighted attic story. Prior to the factory system, the workers had been scattered among their own homes, but when mills began to require perhaps hundreds of operatives who could not live far from their work, the industrialists had to house them. Many of the early 19th century mill villages were composed of individual houses for families or of boarding houses for unmarried workers, simple and unpretentious, but not necessarily crowded and as well equipped as ordinary homes of the time. The housing of the Amoskeag cotton mills, Manchester, N. H., was excellent, while charming mill villages shaded with elms are scattered through Rhode Island and Massachusetts. The slums, commonly associated with company housing, are generally later in date.

One of the first modern factories was the AEG¹ turbine factory, Berlin (1909), designed by Peter Behrens. Its simple but powerful masses

end of this quarter-mile-long building facilitate a continuous process of manufacture and assembly from the entry of raw materials on the ground floor to the finished cars on top. One may drive through the whole factory; even the roof is used, as a testing track for the product. The concept of the wall as a skin to exclude weather instead of a necessary support for the floors and roof has been made possible by steel or concrete construction. Peter Behrens and Alexander Popp placed all the supports inside the walls of the Linz factory (1934) for the Austrian State Tobacco Monopoly, so that unbroken strip windows light each of the six floors. This outer skin is carefully insulated to maintain the even temperature and humidity required for the product. Bright colors enliven the interior, while medical offices, a restaurant, baths, and a kindergarten provide for the welfare of the workers. Even more striking is the printing plant for the *Daily Express*, London, where H. O. Ellis and Clarke separated their strip windows with bands of black

¹ Allgemeine Elektrizitäts Gesellschaft.

glass. They also installed at the top a track to hold running cradles when the facing or the windows need cleaning. All these buildings except the power plants have been several stories high; multistory buildings occupy less land and cost less to construct than single-story buildings of the same floor area. Nevertheless, for many manufacturing processes the advantages of conducting all the operations on a single floor may overcome the higher cost of land and building. The Lady Esther, Ltd., office and factory, Chicago, designed by Albert Kahn, illustrates this trend to single-story buildings.

EVERARD M. UPJOHN,
Professor of Fine Arts, Columbia University.

INDUSTRIAL ARTS EDUCATION. Industrial arts education is the broad study of the materials, organization, tools, processes, products, jobs, and human problems of industry. It has also been defined as a study of the changes made by man in the forms of materials to increase their values, and of the problems of life related to these changes. As such, industrial arts education is essentially a phase of the general education of every individual who lives in an industrial society. It is that aspect of general education which deals with industry and with the problems that emerge from the dynamic nature of an industrial and technological society. Industrial arts education is not to be confused with industrial education, technical education, or with the generic term vocational education. These terms are used to identify that special education whose controlling purpose is gainful employment, or the preparation for specific jobs in industry.

Educators have carefully set forth the aims and objectives of industrial arts education. The objectives are specific and they are conceived of in terms of desired behavior changes that should take place in the thought and action patterns of those who experience the activities of the industrial arts laboratory or shop. Among the objectives most commonly listed are the following: (1) to satisfy that creative desire in every person to construct something with tools and materials; (2) to develop basic skills in the use of the more common tools and machines, together with a knowledge of the working characteristics and uses of industrial materials; (3) to develop the ability to do simple repair and maintenance work in the home; (4) to afford opportunities to discover individual aptitudes, abilities, and interests in trade and industrial occupations; (5) to offer an interesting and challenging field of possibilities for the development of worthwhile leisure-time activities; (6) to assist in a more intelligent and discriminating selection, appreciation, and use of industrial products and services; (7) to develop an appreciation of appropriate design, sound construction, and good workmanship; (8) to develop habits of orderly methods of procedure in planning and performing tasks; (9) to develop an appreciation of the importance of the concept of work and a respect for honest, careful, and effective work; (10) to develop an active interest in industry and industrial life as a vital approach to an under-

standing of contemporary life; (11) to offer opportunity for the practical applications of mathematics, science, and drawing; and (12) to contribute to the enrichment of all learning activities in the total program of general education.

Industrial arts education, under a variety of names, has had a long history of development and its present position in the school program rests upon four fundamental postulates. Briefly stated these include the following: (1) that a study of the nature and needs of individuals is basic to a sound program of education; (2) that a study of the material culture of American society is a perspective through which great world civilizations can become more meaningful; (3) that a study of the socio-economic forces and conditions which characterize present-day industrial society is vital to an understanding of some of the perplexing problems of contemporary life; and (4) that a study of educational thought and practice through the ages reveals much concerning a philosophy of work and of the nature of handwork and creative activity with tools and materials as strong supports of a balanced education.

Industrial arts education emerged from what is often termed manual training. The emphasis of manual training was on hand skill, chiefly in woodworking. Exercises in wood and in metal characterized manual training and the program reverted often to the practice of some few skills that were believed to have direct vocational bearing. As part of the manual arts movement in education in the last decades of the 19th century shop work in the schools still emphasized manual skills directed to the making of both useful and well designed articles, still principally by hand. This phase of the development of what is now called industrial arts education was tremendously influenced by the introduction of sloyd work from Sweden into the United States by Larsson in Boston in 1888. Following the introduction of manual arts work into the schools came considerable work in the arts and crafts. The phenomenon of industry, however, was not injected into manual arts education. It was not until after the turn of the 20th century that such educators as Charles Russ Richards, James Earl Russell, and Frederick Gordon Bonser began to talk of industrial arts education as a broad orientation or exploration of the world of contemporary work. Industrial arts education calls for a diversity rather than a specialization of skill. Many materials were suggested for use in connection with the introduction to the basic techniques employed in industry.

The program of industrial arts education in the modern elementary school becomes that of aiding the classroom teacher with the many problems relative to developing integrated activity programs. Here the curriculum evolves from the many factors of daily living and rotates around such experiences in child life as food and clothing, or the home and community life. Activities are many and varied and include such things as manipulating, experimenting, building, constructing, reporting, observing, and visiting. Such activities might include the many problems involved in planning and constructing a miniature airport or producing and staging a puppet show.

The adolescent age of the junior high school, the level on which industrial arts education is found in its greatest development, is a noteworthy period of exploration in the child's life and, as such, offers an ideal time for experiences

provided by a well organized and competently taught program of orientation and participation. One state, a leader in industrial arts education, suggests six areas for such exploration and participation. These are the areas of woodwork, metalwork, printing, textiles, ceramics, and electricity. Other programs include work in transportation and in power. With such a rich program the pupils can make a comprehensive study of a number of industries and actually participate in laboratory experiences working with the tools and materials of these industries.

Provision for additional work on the senior high school level in industrial arts education permits more advanced work and a more searching study of industry and the problems of a technological society.

The methodology developed by industrial arts educators merits attention. Some programs feature the comprehensive general shop, a shop in which provision has been made for activities involving many areas of work. An especially broad comprehensive general shop might include as many as four, five, or even six areas selected from wood, metal, printing, textiles, ceramics, and electricity. Other programs, and these are more frequently found in the larger centers or schools, favor the unit general shop, a shop that provides for a wide range of activities in one area of work. Such a shop might be a general unit metal shop in which such aspects of metalwork as forging, foundry work, sheet metal work, art metal work, machine shop might be taught. In the case of the unit general shop, the pupils are usually rotated through a number of shops so that they may experience work in a number of areas.

The industrial arts shop of a modern school always includes a shop library of resource materials, a planning center, and the various working areas where the pupil is able to duplicate and actually reproduce actual industrial experiences. To the pupil, the industrial arts shop becomes an experimental laboratory in which he may test and compare, check and analyze, and create new and varied applications of the principles and practices of industry. He may make hand-made paper, bind a book, develop a ceramic glaze from the raw materials, develop a pattern for casting a power jig saw, design and construct a table or a chair, knit a cravat, develop a photolith process, or build a radio. The human relations aspect of industry also finds its reflection in the modern industrial arts shop. A pupil personnel system enables pupils to obtain valuable experiences in controlling their own activities. This system usually includes the designation of a general superintendent, a tool foreman, a librarian, and a foreman in charge of each work area. These assignments are rotated among the pupils so that each one may have his chance to assume responsibility, to exercise his bent for leadership, and to take directions from his fellows.

As a phase of general education in an industrial society, the program of industrial arts education has grown tremendously. In most school systems work in industrial arts is required of all children in the junior high school. Both boys and girls participate in the shop activities and these activities have expanded greatly. Industrial arts education has assumed an important place in the American schools.

INDUSTRIAL DESIGN. Industrial design is a profession comparatively new to our culture, allied with, and stemming from, mass production. It is, further, the profession which seeks the integration of industry with our culture—a merger which to date has not been entirely accomplished.

In previous periods we have found that the artist-craftsman utilized whatever technical innovations came his way and designed for them; but the Industrial Revolution was so overwhelming in scope that it has taken many decades for the machine to be recognized as the successor to handicraft and to realize its rightful position in our culture. Industrial design is the art of the machine, and as such is a completely different medium of expression from handicraft. Household objects, once the realm of the skilled artist-craftsman with resultant limited production and high cost, could, with the advent of the machine, be produced in vast quantities at low cost and, therefore, quickly reach a majority of the population.

Man has always had a tendency to style those articles he possesses, as his response to beauty is inherent and, given a choice, he will always select that which is beautiful. The industrial designer, then, is the artist in the service of industry. Essentially, he is a sculptor who combines his creative talent and knowledge of three-dimensional form with modern technology. His main concern is the appearance factor of those products made in mass by the machine. He relates his aesthetic values to the total problem of a factory-made object which includes consideration of function, materials, tools, manufacturing processes, and economy. He is keenly aware of the end product which rests on the sales counter or sales floor and finally in the home. His is the duty of successfully combining and relating three different points of view: the manufacturer's, the retailer's, and the consumer's. His main contribution is a contemporary art expression in everyday objects.

Evolution of the Designer in Industry.—In the early stages of mass production, the potentiality of power-driven machinery was not fully understood by manufacturers, whose first thought it was simply to increase production and consumption of the many household items once made by the costly hand method. It is not surprising, therefore, that the earliest machine products borrowed a great deal from their handicraft predecessors, thus producing a synthetic art, a veneer as it were, for the artisan-craftsman brought inspiration to his work and it reflected him and his age. Early examples of machine art in its own right are rare; for the most part manufacturers were content to imitate the past and accept the limitations of tradition, counting machine products merely as a substitute for handicraft. As an example of this, we still find the art forms of other cultures indiscriminately applied to present day objects. Chippendale, Sheraton, Duncan Phyfe,

INDUSTRIAL DESIGN

Mass production design for liquid containers to be used in refrigerator.

Three-dimensional design in plaster on the moldmaker's jolly.

Adams, and Hepplewhite are historic names in household furnishings, but the machine inherently was not meant to imitate these styles, a practice which has existed for so long a time. The transition from applied design to functional design was slow, and in some areas has yet to occur.

More recently, the value of the power tool has come to be understood, but it is only in the past decade that the industrial designer has been recognized as a specialist in his own right. It is obvious that in an economy geared to production traditional styles cannot be copied to infinity. With the artist-craftsman almost extinct, the market became glutted with synthetic styles of the past with no new shapes to represent this new era.

As standardization implies both quantity production and broader distribution, the emphasis must be placed on the product rather than its method of manufacture. (The use and design of the automobile, for example, concern most of the people in the country, but the process of manufacture concerns only the planning unit and production crews in the factory.) All the thought and skill of the specialist must thus be directed to shaping a perfect, or near-perfect model suited for both mass production and mass acceptance. The lack of consumer acceptance soon became a problem with which the manufacturer had to cope. The earliest attempts to alleviate this state of affairs were characterized by an ugliness resulting from a lack of the artist's hand. Factory engineers and foremen took a step in the right direction when they cast off the applied design of alien traditions and began production of the unadorned shapes which are characteristic of the machine; but that solution which is usually satisfactory to an engineer or factory foreman may be extremely unpleasant to the buying public. The first machine designs were no more pleasing than the machine-produced handicraft designs. The situation demanded the talents of a person who could not only understand the technical aspects of producing an article, but also one able to relate the final appearance of the product to these technical aspects and to the psychology of mass acceptance as well—in short, what was needed was the industrial designer.

The first designers for industry were not industrial designers as such; rather, they were men of creative sensibility drawn from the allied fields of fine arts. These sensed the possibilities inherent in the machine at a time when the general population sensed only the ugliness of the whole factory system, from the slums it created to the bad replicas of hand-made objects. Theirs was a difficult task, with the level of good taste at its lowest in the history of the world. The harsh and unharmonious engineer-produced shape at the turn of the century was the basis of a reaction in the English arts and crafts movement which reached its height on the Continent under the leadership of such men as Josef Hoffman and Henry Clemens Van de Velde in a style now known as *art nouveau*, characterized by extreme curvilinear forms. *Art nouveau* (also known as *Jugendstil* or "Style 1900") was international in character and the first decorative movement to actually break with the trends of eclecticism. But it was not until the Bauhaus (1919-1929), the famous design school in Dessau, Germany, under the leadership of the architect Walter Gropius, that the art of the machine came of age. Many of the great names of modern fine arts are associated

with the Bauhaus, and here we find the machine age influencing the fine arts as well as the fine arts influencing the machine product. The Bauhaus movement was more and more in the direction of machinelike simplicity typified by Marcel Breuer's chair of tubular steel. The architect Charles Edouard Jeanneret, known as "Le Corbusier," defined the house as a "machine for living" and with Jacobus J. P. Oud of Holland and Mies van der Rohe built structures of precision simplicity and functionalism based on geometric shapes. The integration of industry and culture had begun. The experiments at the Bauhaus in designing with new materials and with problems in the interrelation of space gave rise to the constructivist movement in sculpture and thence to the application of these principles to the design of household articles as well.

The Art of the Machine.—The art of the machine is essentially devoid of surface ornament, and is characterized by precision, simplicity, and ease of duplication, in contrast to handicraft which is irregular, unique, and difficult to produce in quantity. The two are, as has already been pointed out, completely different mediums of expression. The ancient Roman architect, Marcus Vitruvius Pollio, stated that architecture should contain three elements: utility (or function), strength or vitality, and beauty. These qualities are still valid and could be applied to any of the arts serving man's needs—especially industrial design, the art of the machine. While a great deal of energy had in the past been expended in the advertising or visual presentation of the product to the consumer, it took a long time for manufacturers in general to recognize that art qualities need not be confined only to painting and sculpture but may be present in all of the products made by man.

The manufacturer came to realize that these qualities are universal, with universal appeal, and that they do not necessarily forego mechanical efficiency. The machine art experiments at the Bauhaus attracted the attention of the intelligent creative artist who saw in true machine forms not ugliness, indeed there was beauty in sheer surfaces and abstract shapes. It was only necessary to adapt these qualities in order to achieve a harmonious beauty in the finished product—to bring in delicate perceptions and a fine sense of subtle relationships of form, color, balance and unity, and to study these factors in relationship with the technological aspects of factory production.

Cultural Determinants in Design.—The world we live in today was shaped by the Industrial Revolution; our culture and economy are based on mass production. In contrast with the agrarian civilizations of the past, where nothing changed greatly from year to year, the pace of our life is quick indeed, and becomes the more so as technical advances continue at a rate unimaginable by our forebears. We are dependent on the machine and on the specialist, for with the power tools comes a division of work; an employee becomes a single link in a long chain of production, doing one step or part in an entire manufacturing process. The machine has brought us an increase in the standard of living. Today the many household articles that once might have been a luxury to be enjoyed by very few are within the reach of everyone. Indeed, they are no longer "luxuries," but are now considered "necessities," and the fact that they are so considered is further

An example of the graphic method of presentation and design development (often called the "explosion" drawing), which demands thinking three-dimensionally through and around the form. Mere two-dimensional drawing so often represents surface thinking only, and is, therefore, inadequate from the standpoint of full design development prior to production—a concept so essential in designing for mass acceptance.

proof of how far our culture has progressed. The work day is shorter, allowing more time for leisure and interests outside of earning a living. Vitality has improved and the importance of the human being has been strengthened. Evidences of man's ingenuity are all around us, being especially visible in the cities where natural forms are, for the most part, replaced by those which are man-made. The structures that house us and our activities and the multiple objects necessary for our daily existence are determined in form by their own purposes. There is a never-ending procession of new forms coming into being. Some replace worn out or obsolete items; others are entirely novel in appearance and utility with new needs served by new shapes. Control of new shapes then becomes the work of the engineer who solves the mechanical problems and the industrial designer who works with him to solve the functional and appearance problems. Unlike his predecessor, the artist-craftsman who thought in terms of one item made with simple tools, the industrial designer thinks in terms of large quantities produced by complex machines. His concern is not in achieving aesthetic appeal by a final rub-down coat of varnish on a breakfront, but to achieve a design containing aesthetic satisfaction while employing new techniques and materials and meeting new demands. Above all, the shapes he employs are not derivative. They belong to no period and have no traditional imprint. They are, instead, thought-out contemporary shapes, formed by need, science, and aesthetics, and are, moreover, true expressions of our civilization and culture—just as the shapes of the past are reflections of past cultures.

Function or Utility as First Concern of the Designer.—There is a purpose to all shape. Sculpture seeks to attain pure aesthetic quality at the highest and purest level. Common articles should contain beauty with function. The purpose of a statue is aesthetic but the teacup must hold a given amount of hot liquid to fulfill its purpose. The statue belongs on a pedestal; the cup belongs on a table. Both take their place in the expression of a culture. The function of the object is, therefore, the first concern of the designer. With the function begins the shape. Man is the designer's measure; man's environment at home, at work, at play, is of prime importance. Distances and proportions are based on the size and movement of the human frame and ideally should take into consideration psychological factors as well, for man is more than his physical size. The finest appearance in the world will hardly fulfill the requirements of a chair if it is incapable of containing a person comfortably and securely. Close observation of normal human activities is essential to the industrial designer who might be thought of as a "human engineer."

Strength or Vitality as Factors in a Design.—Vitruvius's quality of strength or vitality can probably best be defined as honesty—truthfulness to the age in which the design is produced and to the materials and manufacturing processes involved in its making. We have already noted that early machine-made items lacked this quality, being derivative or eclectic designs rather than true creative forms. The Gothic cathedral was an honest expression of its time, but it cannot be said that the Louis XV legs on the gas stoves of only a few years ago were expressive of our way of living. In the same way, the materials of which the product is made should be expressed with

honesty as they have an integrity of their own, and in the hands of a competent designer can fully express their individual beauty. While the simulation of one material by another may be an interesting technical feat, it is most surely bad economic practice and worse design. We are all familiar with the feelings of distaste attendant to the "cheap" or copied. Metal, being metal, should be handled as such. Attempts to give steel the appearance of wood neither fully succeed in doing so nor properly utilize the possibilities of the material. The designer will familiarize himself with the inherent qualities of many materials and will, consequently, be able to design with equal ease for any given one.

The tools and processes required in the production of any article will have their effect on the nature of the design and leave their imprint and character in the material. The design should also honestly represent its means of manufacture. The hand-carved motifs on much of the furniture of the past cannot honestly be duplicated by machine since the great value of these pieces lies in their slight irregularity and in the loving care lavished on them by skilled hands over a long period of time.

The economic factor in the production of the design will require the artist's full utilization of his ingenuity in handling well his materials and processes, for while it may be possible to produce by machine anything at all that a designer might conjure up, it is hardly feasible to do so unless it will find acceptance with the buyers. The cost of manufacture of any item and its intended market will be one of the major determinants of its character.

Beauty or Fine Appearance in a Design.—Beauty or fine appearance is one of the most elusive factors involved in designing and is, of course, closest to the designer's interest. While there is no satisfactory universal definition of beauty, the design will incorporate elements everyone will agree are related to beauty; timeliness; vitality and honesty of expression; subtle harmonious relationships between colors, textures, areas of thickness and thinness; and balance of all the forces in the design—all elements which might be called good taste. It should be emphasized that the fundamental requirement for the designing of beautiful objects is not enthusiasm or persistence, although both are necessary, but talent.

An example of recent industrial designing that will probably remain a classic is the series of chairs by Charles Eames. These chairs possess all the qualities that have been mentioned and represent true creative designing for the machine age. They have been designed for the human figure in the seated position and are light enough to move about easily; they employ the latest materials and manufacturing processes; they are fine functional shapes entirely suited to our way of living with no excess ornament. The shape itself, rising from its function, is aesthetically pleasing and needs nothing applied.

The Training of the Designer.—With the recognition of the need for specialists in the art of the machine, art schools began to set up courses to meet this need. College degrees were first offered in the field of industrial design in 1936 and there are now a number of excellent courses in schools throughout the country with industry participating in some cases by offering scholarships. In addition, some liberal arts schools

DEVELOPMENTS IN CHAIR DESIGNING INFLUENCED BY THE MACHINE AGE.

(A) The Thonet chair of bentwood is a lightweight, rigid structure weighing considerably less and having fewer parts than a conventional wooden chair. (B) The Breuer chair is an early example of economy in design using tubular steel. (C) This Alvar Aalto chair is an early example of lightweight laminated plywood. (D) The Eero Saarinen chair is made of formed plastic with foam rubber. (E) The "bucket seat" chair by Eames is molded of fiberglass-reinforced polyester plastic. (F) The "Barcelona" chair of Mies van der Rohe is a functional, aesthetic expression in steel, foam rubber, and calfskin.

offer descriptive courses in or relating to industrial design. Most courses in industrial design are four-year programs. Successful completion of such a course is gradually coming to be a prerequisite for employment as more and more the trained designer is being consulted in the case of many inexpensive items as well as high-priced articles (which represents a tremendous achievement in so young a profession). A well balanced program will include the liberal arts, technical subjects, and, most important, thorough design training and aesthetics.

The liberal arts subjects will give the prospective designer the broad academic background necessary for successful living in the world of

today with an appreciation of his place in history as well as an appreciation of the achievements of the past. The technical subjects will enable him to appreciate new materials and techniques—all problems of the engineer with whom he will later work closely. His art or design training will produce creative thinking as a result of consideration of these other areas.

Three-dimensional design is the most important area of aesthetic training for the prospective designer. His first experiments in three dimensions will be in sculpture where he will relate tectonic shapes and plastic forms to abstract designs. Tectonic implies building or construction, therefore, tectonic shapes would be fabri-

cations where thin sections or planes are arranged into an agreeable pattern which moves in space to the maximum degree. This same principle is the basis of architecture and is called architectonic when applied to that field. Tectonic form study would begin with constructions in abstract sculpture and terminate with experimental design problems in subdivisions of architectural enclosures in terms of interiors, furniture, and furnishings. Plastic form is not fabricated or built in sections but always appears as an integral unit as if poured from a mold. It is the development of convexities and concavities and consists of modeled surfaces where all planes flow into each other, rather than the juxtaposition of planes as in tectonic forms. Plastic form in the sculpture of convex or concave figures or abstract shapes would lead into designing the plastic forms of many everyday objects, from an automobile to a handle.

While two-dimensional design is an important facet in the training of the industrial designer, it should be stressed that the development of good graphic technique alone will not make an industrial designer who will always be dealing with three-dimensional problems. Empathic sketching (literally, a feeling into the design of the emotional stimuli from the problem object), a course in the art of brevity in graphic expression, will enable the designer to record his ideas rapidly preliminary to studying the dimensional aspects of the shape, but these ideas on paper are a very different thing from the three-dimensional realization of the form. Even a very simple, easily comprehended shape, such as the cylinder, can be deceiving in its appearance on paper which is usually different from its appearance in the round. So many industrial products have been unsuccessful for this very reason—they began and ended on the drawing board. For the most part, two-dimensional representation will be used as a means of presenting the form after it has thoroughly crystallized in three dimensions and a series of models made. Hence two-dimensional design is the medium particularly suited to the advertising or illustration of a designed form.

The training will also include model making, use of power tools, mold making, and photography. In some cases, where equipment permits, a complete factory problem will be simulated. Experimental design familiarizes the student with materials, structures, and production methods, and is usually taught with the assistance of advisors from industry.

The field continues to expand with the expanding economy and also with the growing aesthetic consciousness of a good portion of the public. Design studios are now essential departments in every major manufacturing enterprise, and a good number of smaller ones have design staffs or hire free-lance designers. Styling sections can run into several hundred persons and include engineers and technicians along with the designers. These will usually have a definite program for apprenticeship with special and advanced training in the particular problems of the company, procedures of the studio, nature of the articles to be designed, factory set-up, and types of market.

After graduation from a recognized school the designer's orientation is usually short and he becomes a permanent member of the staff in only several months. In a studio or small group, the newcomer is assigned to an experienced

designer for a short period. Later he works as an associate or is given an assignment of his own.

There are two national organizations: the Industrial Design Institute (IDI), and the Society of Industrial Designers (SID). Both have regional and city chapters throughout the country. A code of ethics to protect both manufacturer and designer has been devised as industrial design seeks to ally itself with the group of professions which maintain recognized standards and whose practitioners meet fixed standards.

ROBERT A. KÖLLI,
Consulting Designer; Chairman, Industrial Design Department, Pratt Institute.

INDUSTRIAL EDUCATION. The belief that training for work is not only a necessity but a valuable ingredient in acquiring a complete education has long existed. The generic term used to cover that aspect of education whose controlling purpose is gainful employment is vocational education (q.v.). Industrial education is that part of vocational education which prepares people for occupational efficiency and adjustment in one of the many callings in the areas of industry and trade. Vocational education is concerned with the development of the individual both as a person and as a worker; it is that phase of an individual's complete education for functional citizenship that prepares him for maximal occupational adjustment and gainful employment. Industrial education is characterized by its central purpose of providing experiences whereby an individual learns successfully to engage in an industrial occupation, to appreciate and understand the common cultural heritage, and to participate effectively in civic affairs. In a very strict sense the term should be vocational-industrial education and should be classified along with such branches of vocational education as vocational-agricultural education, vocational-technical education, vocational-business education, and vocational home economics education. Industrial education is not to be confused with industrial arts education. This last term may be defined as that part of the general education of all citizens in an industrial society and is the study of the changes made by man in the forms of materials to increase their values, and of the problems of life related to these changes (see **INDUSTRIAL ARTS EDUCATION**).

Education for industrial pursuits is as old as civilization itself. In primitive societies at the dawn of history, the members of the community were inducted into the occupations necessary to sustain the life of the tribe and they were trained for these occupations. In the complex and highly technical economy of present-day industrial societies, individuals must learn to participate effectively in some area of the work to provide the food, clothing, shelter, and services necessary to maintain and to advance standards of living.

Industrial education serves many groups in 20th century societies. The pre-employed group seeking initial entrance into the world of industrial work may be served in the all-day school. Such full-time schools are known by a number of names. Among those in common use are vocational schools, industrial high schools, and trade schools. Young workers who are in occupations that for one reason or another they do not wish to make their life work are served by part-time or evening programs of industrial education.

Those who are already at work in industry and who wish to prepare themselves for wider service or more advanced jobs may be provided with programs of in-service or up-grading industrial education. In the highly skilled trades, a modified form of apprenticeship serves as the program of industrial education. Workers in declining industries and the unemployed may be retrained for new industrial jobs in programs of industrial education especially designed to meet their needs. Increasing attention is now being given to programs of industrial education designed to rehabilitate those handicapped through injury or disease whether acquired or existing since birth. These last programs seek to prepare these people for entry or re-entry into the world of productive employment.

The wide range of services that industrial education may render to the community implies the existence of numerous agencies to carry on such diversified activities. Some of these agencies are private; some are public. Many of the programs are provided by the schools while others are given under the aegis of industry itself.

Industrial education of less-than-college grade and under public auspices is federally aided in the United States. Under the terms of the Smith-Hughes Act (the National Vocational Act of 1917) federal funds as grants in aid are available, under certain conditions, to provide for cooperation with the several states in promotion of industrial education. The George-Barden Act of 1946 provides for the further development of certain types of vocational education, including industrial education, in the several states and territories and amends and extends the provisions of the Smith-Hughes Act. Additional amounts of money, too, may be appropriated under this second federal law.

From the early stress on manual skills and related technical knowledge that characterized the programs of industrial education for the pre-employed group in the first four decades of the 20th century, trends may be identified which indicate a change in philosophy and in practices. New York City, for example, sees the vocational high school as an agency to provide a well-rounded, fully balanced program of secondary education. This great industrial metropolis is concerned that the pupil be educated for life as well as for a livelihood. The industrial high school pupil, it is pointed out, is no different from any other adolescent in his need for character and personality training; for the development of correct habits, attitudes, ideals, and standards of conduct; for the acquisition of the virtues of loyalty, diligence, honesty, truthfulness, kindness, courtesy, and respect for authority. The aims of industrial high schools may be stated as follows: *Character*—to insure the basis for rich, useful, ethical living in a society promoting the common welfare; *Our American Heritage*—to develop pride and faith in American democracy, including respect for the dignity and worth of individuals and people, regardless of race, religion, nationality or socio-economic status; *Social Relationships*—to develop desirable social attitudes and relationships within the family, the school, and the community; *Economic Relationships*—to create an awareness of economic forces and an understanding of their impact on all who serve in the world of work; *Thinking*—to develop reasoning based on adequate hypotheses, supported by facts and principles; *Skills and Knowledges (Academic)*—

to insure a command, in accordance with ability, of the common integrating knowledges and skills; *Appreciation and Expression*—to promote the appreciation and enjoyment of the aesthetic and cultural aspects of living, and to foster powers of creative expression; *Health*—to develop and maintain body and mind in sound, wholesome condition; *Exploration and Guidance*—to discover and direct desirable individual interests, aptitudes, and abilities and on this foundation to encourage a wise choice of educational, vocational and social goals; *Occupational Competency*—to establish useful occupational knowledge and skills, assisting each individual to reach his highest level of accomplishment; and *Vocational Adjustment*—to enable satisfactory adjustment in vocation. Toward pupil attainment of these social, personal, and vocational competencies, the industrial high school curriculum should include: (1) participation in democratic citizenship, (2) cultivation of capacities for the fullest enjoyment of life, and (3) education for work.

Industrial high schools designed to prepare adolescents for initial industrial employment are of several sorts. The general industrial high school provides programs in a number of trades. Such a school might offer programs for boys in automotive repair and service, cabinet-making, carpentry, commercial art, commercial photography, electrical construction and maintenance, food service, machine shop, masonry, sheet metal, and tool and die making. For girls, such an industrial high school might have beauty culture, trade dressmaking, food service, business machines, commercial art, and fashion illustration.

In the larger cities there may be central industrial high schools which provide training for the numerous areas of an industry or trade. A food trades industrial high school might offer programs in baking, butchering, cafeteria work, and retail grocery store work. A needle trades industrial high school might have in its curriculum courses in apparel manufacturing, pattern making and design, fashion design, pattern draping and design, power machine operation, millinery, trade dressmaking, shoe and leather goods manufacturing, and fur garment manufacturing. In order to extend the services of industrial education and provide such training for more and more individuals, the schools have developed a structure called the area vocational school. This is a school that serves a large geographic area such as a number of cities, a county, or a section of a state. Communities too small to support a vocational school may enter into a contractual agreement and join together to provide a centrally located vocation school developed to serve the needs of the wider area. Another adjustment designed to meet the needs of those seeking industrial training is the cooperative industrial program. An industrial cooperative program is one that provides industrial training by sharing the services available in the school and utilizing the shops of local industrial establishments. In an industrial cooperative program a student spends part of his time in the school and part of his time working in an industrial plant. The arrangement of time may be on a half-day basis, or a week-to-week basis. All of the time, however, the pupil is under the supervision of the school and the supervising agent is called a teacher-coordinator. It is the task of this school person to integrate the work of the shop with the work of the school in the case of each cooperative student. This program permits the

very real experiences of industry to be coordinated with the learning process. It also permits a student to earn while learning because while in the industrial shop the student is on the payroll of the employer.

Industrial education has closely followed the development of industry in the United States. With the rise of manufacturing to a place of paramount importance following the Civil War and with the growth of the service trades during the first half of the 20th century, industrial education has been extended throughout the country and the programs have been enriched and widened. Federal grants in aid, too, have acted as stimuli to the development of the programs under public auspices.

Following the pattern outlined in the Smith-Hughes Act, the school day for the pre-employed group is divided into three parts; at least half of the time is given over to useful or productive work in the shops while the remainder of the time is devoted to studies related to the trade and to general social and civic education. Another pattern which has developed from the traditions that surrounded industrial education and which has been fortified by the acts that provide federal aid is the separate industrial school. In many cities there is a division between the industrial or vocational high schools and the academic high schools. The programs are in different school buildings and supervised and administered by different personnel. Educators are currently questioning this practice and they point to the fact that each individual is entitled to both general and specialized education. The all-purpose or comprehensive high school has been developed to bridge the gap between the academic high school and the industrial high school. The comprehensive high school which has appeared in many communities offers both academic work and vocational work.

Although stress has been laid upon industrial education for the pre-employed group, by far the greater number of individuals pursuing industrial education are enrolled in part-time courses that follow the day's work. In evening programs of the public schools, in the day and evening sessions of the private trade schools, in factory schools, in foremanship training classes, in numerous on-the-job training programs, in schools conducted by labor organizations, in apprentice training programs, and in vocational rehabilitation centers are thousands of individuals seeking to become occupationally efficient in the skills and habits necessary for industrial employment.

Industrial education in the United States has reacted to the pressing emergencies in the nation's history. The Smith-Hughes Act was passed in February 1917 and came just at the time when skilled workers were needed for the war-supporting industries and when sources of skilled workers from Europe could no longer furnish such a work force. In the years of the great depression, following 1932, numerous federal agencies sought to provide industrial training for those out of regular employment and for those youth who could find no employment. Following Pearl Harbor, the federal government took the leadership in the training of workers for the war industries. Through federal subsidies and in cooperation with the several states thousands of workers were trained in the skills vital to industrial production in a war-time economy. At the termination of hostilities, many veterans took advantage of the educational provisions of the various servicemen's

acts and enrolled in full-time and part-time courses in industrial education.

The development of a program of industrial education to meet the needs of a community is a problem for cooperative effort. The needs of individuals must be identified and met and likewise the absorbing capacity of the industries must be estimated. Several groups in the community are vitally concerned, namely the youth (and their parents), management, labor, and educators. In many communities provision is made for industrial education advisory committees charged with the responsibility of developing policies and plans for programs of trade education. These advisory committees are usually composed of representatives of management, labor, education, and the general public. In many states advisory committees are authorized by law and required to be set up. Advisory committees have in many cases proved remarkably effective in promoting sound programs of industrial education.

Looking back over the long history of industrial education, certain landmarks stand out. Throughout the Middle Ages, the apprenticeship system provided the general and industrial education for those who sought their livelihood in the secular trades. Apprenticeship as a form of industrial education persisted down through the years to the advent of the factory system and the age of power-driven machinery. It is still functioning today in certain skilled trades. With the coming of the factory system and the evolution of modern industry, the apprenticeship system of the middle centuries was no longer appropriate as a universal method of providing workers for the skilled, semiskilled, and unskilled vocations. New programs of industrial education had to be devised and the schools were looked to to supply these. Again, following the devastating wars of Reformation and post-Reformation eras, humanitarian leaders sought to care for the homeless war orphans. Others sought to provide a functional education for those in penal institutions. Both groups saw in industrial education a way to provide for the reclamation of these unfortunates. In the years of the first Napoleon, France established great military and technical schools that served as models later for other European and American schools. With the rise of the German Empire after 1870 and with the rapid industrialization of the new united Germany, that nation developed important technical schools and continuation schools designed to provide workers with the skills necessary in the occupations of a highly technological society. In England, the workingmen's colleges and the mechanics' institutes of the United States are parallel manifestations of the interest in the further education of industrial workers.

As the United States enters into the second half of the 20th century it is reasonable to assume that continued strides will be made in technology. New materials, new machines, new powers, and new methods will undoubtedly characterize American industry. It is to be expected that industrial education in the future will reconstruct itself in order to provide the educated labor force competent to assure the further development of the American experiment in industrial democracy.

WILLIAM P. SEARS,

Professor of Education, Department of Vocational Education, New York University.

INDUSTRIAL ENGINEERING, a science which has as its basic objective the provision of conditions which will permit the accomplishment of a given task in the least possible time, at the lowest total cost, with the least effort, and with the most satisfaction to the people who must do the work. It is the engineering approach applied to all factors including the human factor involved in the production and distribution of products or services.

Industrial engineering derives its name from the fact that it was first used by industry. Its initial use was largely confined to the factory. Although this continues to be its principal area of application, the industrial engineering approach was later found to be equally valuable in the office and in nonindustrial enterprises such as hospitals, hotels, libraries, and even in agriculture and in the home.

Because almost every activity of a business has its effect on the ultimate cost of the goods or services it produces, it is often difficult to make a clear distinction between industrial engineering and scientific management. In the period which immediately followed the development of scientific management by Fredrick W. Taylor at the beginning of the 20th century, industrial engineering in the language of the factory was considered to be nearly synonymous with time and motion study. With the passing of time, however, the industrial engineer found it desirable to include a consideration of more and more factors in his studies. His interest in quality, for example, led him into the field of quality control. Similarly he came to include among his specific interests such techniques, systems, and procedures as production control, budgets, standard costs, tool design, methods engineering, wage incentives, job evaluation, office procedures, and a host of others. As a background for his activities, he drew upon mechanical engineering, economics, sociology, psychology, philosophy, accountancy, and the like, welding the phases of these sciences which affected his activities into a new science.

It is quite difficult to differentiate between industrial engineering and management engineering. In popular usage, management engineering is considered to be a somewhat broader term including fields such as organization and administration which are not usually felt to be part of industrial engineering. The distinction is not clear cut, however, and the industrial engineer as he grows and broadens his experience is likely to find that he tends to call himself with increasing frequency a management engineer.

In 1943, the Work Standardization Committee of the Management Division of the American Society of Mechanical Engineers began a project of developing definitions for all terms used in the field of industrial engineering. In an attempt to define the limits of this field, the committee prepared the chart shown in slightly altered form by Fig. 1. This chart shows a number of the techniques and procedures which together make

up industrial engineering. It will serve as a guide in the discussion which follows. The chart, however, by no means includes all of the techniques which are considered by one or more authorities as legitimately belonging to industrial engineering. Among the techniques and procedures which with some logic could be added to the chart are: production planning and control, inventory control, quality control, top management controls, plant location and construction, production line techniques, product design, office layout, storekeeping procedures, safety engineering, operator training, suggestion systems, and operations research. Even this list does not include everything in which the industrial engineer is interested.

Although the discussion which follows will confine itself largely to the areas shown on the chart, Fig. 1, which may be regarded as the hard core of industrial engineering, the essential broadness of the industrial engineering approach should be recognized. The history of the development of industrial engineering is one of constant growth and broadening. This is illustrated by the fact that in 1920, industrial engineering was taught in very few universities and then usually as a few unrelated elective courses tacked onto a mechanical engineering course. By 1950, 4-year university courses leading to the degree of Industrial Engineering, or B.S. in Industrial Engineering, were by no means uncommon.

Development of Industrial Engineering.—Fredrick W. Taylor, who is often referred to as the father of scientific management, also laid the foundations for much of what later came to be called industrial engineering. In 1882, Taylor was made the foreman of the machine shop of the Midvale Steel Company near Philadelphia, Pa. He soon recognized that the men whom he supervised were producing only a fraction of what they could produce. Since Taylor was responsible for the efficient operation of his department, this disturbed him, and he began to search for ways of increasing the productivity of his people. At length, he developed a procedure which he described at a meeting of the American Society of Mechanical Engineers in 1903 in a classic paper entitled "Shop Management."

Among other things, Taylor developed a system of time study and finally a formula for getting maximum production. His formula was: *The greatest production results when each worker is given a definite task to be performed in a definite time and in a definite manner.* Modern industrial engineering is based upon this formula, and although the procedures for accomplishing it have been increasingly expanded, developed, and refined with each passing year, the formula is still as fundamental for high productivity as it was when Taylor first advanced it.

In Taylor's time, the *definite task* was specified after a study of the job had determined the best operation sequence. The *definite time* was established by stop watch time study or from standard time data based on time study. The *definite manner*—that is, the method—was developed by painstaking experimentation and was recorded for the information of the worker and his foreman on an instruction card.

Taylor, stimulated in part at least by the work of Frank B. and Lillian M. Gilbreth in the field of motion study, recognized the importance of method. His accounts of pig iron handling, metal cutting, and the like are classic examples of early

Fig. 1. Chart of techniques and procedures commonly included in industrial engineering.

methods studies. The results obtained by stop watch time study and the application of wage incentives in the form of increased production were so spectacular, however, that many of those who subsequently attempted to apply Taylor's techniques lost sight of the factor of method altogether. Their procedure was to time study a job, accepting without question the method being used by the worker, establish a production standard, and then apply it under a wage incentive plan. Large production increases were obtained, costs were reduced, and the work paid off handsomely.

Difficulties developed, however, when production increased considerably more than was expected. Because the method had received scant consideration prior to the application of incentives, many possibilities for improving it existed. When the operator was told that the more he produced the more he would earn, he began to study methods in earnest. In some cases, he found that major improvements could be made. His production—and his earnings—increased far beyond what had been anticipated.

Many managers of that period had the feeling that a given worker was worth only so much. They were willing to see a nominal bonus earned in exchange for a considerable increase in production. But when earnings rose above what they thought was an acceptable maximum, they became actively disturbed. Usually they took action to revise the standard or piece rate, either as the result of an out-and-out rate cut or as the result of a management-made methods change. In either case, the earnings of the worker were reduced, and it did not take him long to realize that it was not safe to earn more than a certain amount. As a result, a ceiling on earnings was tacitly agreed to by the workers, a ceiling which was seldom exceeded thereafter.

This developed into what was apparently a very satisfactory situation during the 1920's. Earnings under piece work or wage incentive plans were quite consistent—because they were pegged by the workers. Standards established by time study appeared accurate, because they produced anticipated earnings. The operators in most cases put in a reasonably full day's work, because the incentive to improve methods beyond a point which permitted the agreed-to top earnings was lacking.

Then came the growth of unionism in the 1930's. With the protection afforded by the unions and union contracts, workers became less fearful of breaking through earnings ceilings. When they found that the union could successfully oppose unjustified changes in standards, earnings began to rise rapidly. Latent methods improvements were put into effect, and earnings went still higher. Some jobs were more susceptible to improvement than others. As a result, inconsistencies in earnings among workers developed which created serious industrial relations problems. As this situation unfolded, the importance of establishing effective working methods prior to time study became apparent. It brought about a management change from an almost complete neglect of methods study, to a more and more detailed consideration of the factor of method.

Contribution of Motion Study.—The tools for the more intensive study of methods were at hand as the result of the pioneer work which had been done by Frank B. and Lillian M. Gilbreth in the field of motion study. In 1885 at the

age of 17, Frank Gilbreth started work as a bricklayer apprentice. On his first day at work, he observed that the skilled bricklayer who was acting as his teacher performed the work in three different ways. He used one set of motions when he was working slowly, another set when working rapidly, and still a third set when demonstrating to his pupil. When Gilbreth asked questions to try to find out the reasons for this, the foreman, thinking that teacher and pupil were wasting too much time in unnecessary conversation, transferred Gilbreth to another instructor. Here again Gilbreth observed the fact that his teacher used three different sets of motions and further that these were different from the three sets used by his first mentor.

Gilbreth's interest in this discovery became the basis for a major contribution to industrial engineering. Some years later, with the encouragement of his wife, Lillian M. Gilbreth, he decided to give up a profitable contracting and construction business and devote himself to the installation of scientific management, and especially to research and application work in the field of motion study. The Gilbreths began making detailed laboratory studies of motions and methods and at length developed a technique known as micromotion study.

As the result of analyzing motion picture films of a large number of industrial operations, the Gilbreths concluded that all manual work is performed by using a relatively few basic elements of work in varying combinations and sequence. They called these elements "therbligs"—the name "Gilbreth" spelled backwards with the "t" and "h" reversed. There were 17 therbligs in the original list known as: search; find; select; transport empty; transport loaded; grasp; release; position; pre position; assemble; disassemble; use; inspect; unavoidable delay; avoidable delay; rest to overcome fatigue; and plan. The micromotion study technique consists of analyzing a method into the therbligs used to perform it, making improvements which will eliminate, combine, or shorten the time for performing as many therbligs as possible, and developing as a result a quicker and easier method of doing the task.

Although the micromotion study technique is entirely practical, the laboratory aspects of the work and the use of unusual terms and symbols prevented many people from recognizing the value of the procedure as quickly as they should. Both Taylor and Gilbreth won many followers in the fields in which they pioneered. Some of these followers professed to see fundamental differences in the procedures developed by these two men, and at length two groups of practitioners evolved. One was the time-study group, and the other was the motion-study group. From roughly 1910 to 1930, these groups considered themselves as opposed to one another. The time-study group could see nothing practical in the laboratory approach, and the motion-study group felt that the time-study group were unscientific and crude in their procedures.

As time passed, however, both groups began to become better acquainted with one another's work, and as is so often the case during the development stage of a new profession, began to realize that they had been calling the same things by different names. The differences were dropped, and the best features of both procedures were combined into an integrated procedure, which the

author of this article and his associates in 1933 called for the first time as far as they know by the name "methods engineering."

The definition of methods engineering which they developed to explain this new term illustrates how the techniques which are the core of industrial engineering were beginning to form a logical pattern. According to this definition, "methods engineering is the technique that subjects each operation of a given piece of work to close analysis in order to eliminate every unnecessary operation and in order to approach the quickest and best method of performing each necessary operation; it includes the standardization of equipment, methods, and working conditions; it trains the operator to follow the standard method; when all this has been done, and not before, it determines by accurate measurement the number of standard hours in which an operator working with standard performance can do the job; finally it usually, although not necessarily, devises a plan for compensating labor which encourages the operator to attain or to surpass standard performance."

Major interest in methods improvement work began to develop in 1930. The United States of America was headed for the depths of the worst depression in its history. Business was almost at a standstill. A buyer's market existed, and competition was strictly on a price basis. Anything which would result in cost reductions was eagerly sought. Hence management was in a receptive mood for techniques which would improve methods. At this same time, the more advanced time study technicians were becoming aware of the incompleteness of their procedures as was pointed out above. Thus the time was ripe for the acceptance of methods study techniques.

In 1932, a book *Common Sense Applied to Motion and Time Study* by Allen H. Mogensen was published. This combined several articles by various men interested in methods study work with some of Mogensen's own experiences in what he presently began to call "work simplification" and gave one of the first coordinated presentations of the methods study practices which had been developed up to that point. Following this came an increasing number of other books, all stressing the importance of methods study. Among the more widely distributed books of this period were *Time and Motion Study and Formulas for Wage Incentives*, by Lowry, Maynard, and Stegemerten, 2d edition 1932, 3d edition 1940; *Motion and Time Study* by Ralph M. Barnes, 1937, 2d edition 1940; *Time Study for Cost Control* by Phil Carroll, Jr., 1938; *Applied Time and Motion Study* by Walter G. Holmes, 1938; and *Operation Analysis* by Maynard and Stegemerten, 1939.

The development of techniques of application of methods engineering and work simplification principles progressed rapidly from 1930 on. At the beginning of this period, the value of process charts, the questioning attitude, micromotion study, and the like as tools of methods improvement were fairly well recognized, but their application during a given methods study was likely to be unsystematic. Too many technicians tended to conduct their studies by concentrating on the correction of obvious inefficiencies, frequently overlooking greater possibilities for improvement. In effect, they often established efficient methods for doing unnecessary work.

Recognition of this caused the leaders in the

field to develop a more systematic approach in the application of methods improvement techniques. The "operation analysis" procedure organized upon the principle of considering first things first was one example of this. It emphasized that there are nine major points or factors which should be considered for every operation studied. These, arranged in logical sequence, are as follows:

- (1) Purpose of operation
- (2) Relation of operation to other operations performed on the part
- (3) Inspection requirements
- (4) Material
- (5) Material handling
- (6) Workplace layout and tool equipment
- (7) Common possibilities for methods improvement
- (8) Working conditions
- (9) Method

The "questioning attitude" tool—that is, deliberately asking why, where, when, what, who, and how about every detail of an operation—a tool used since the time of Taylor and Gilbreth, was expanded to include lists of practical questions to be applied to every step of operation analysis and even to every therblig.

These and similar developments helped to increase the effectiveness of methods improvement activities. The guiding principle of the industrial engineer became "with sufficient study, any method can be improved." Experience showed that this was literally true. The improvements were not always economically justified, but they were possible. Even after a job had been motion studied and improved, it often was possible to improve it still further as the result of more intensive study during which the problem was tackled afresh. A series of improvements could be made until the economics of the situation made further study unprofitable.

Methods improvement activities of this type resulted in many worthwhile economies and contributed importantly to increasing productivity wherever they were applied. They also introduced the problem of technological change and created tensions between management and the workers. The term "methods improvement" implies that an ineffective method is already in existence at the time the study is begun. The industrial engineer studies it, identifies unnecessary or ineffective motions, and by eliminating them improves the method. In effect, he corrects the mistakes which were made when the method was originally developed. His work is methods correction rather than methods engineering. Recognition of this fact led to the next important development in industrial engineering.

Predetermined Motion Time Standards.—It was repeatedly observed that human nature is such that it resists change. Thus when the industrial engineer sought to improve methods by changing old methods into better new methods, he frequently caused resistance or at least resentment on the part of the worker. His work which resulted in increased standards of living for society as a whole and hence was thoroughly desirable at the same time generated human relations problems which it would be better to avoid if possible. They could be avoided, however, only if methods were studied and improved before a job was put into production instead of after.

To do this, it became necessary to develop a somewhat different technique than time and motion study. What the industrial engineer needed, if he was to develop an effective method for

doing a job before production started, was a procedure which would tell him how long it would take to perform any motion sequence he might be able to visualize without having first to train an operator to follow it and then to time it with a stop watch. The use of predetermined motion time standards proved to be the solution to this problem.

The idea of predetermined motion time standards had been attractive to industrial engineers from the very beginning. Taylor visualized a handbook in which the time for performing "every element in every trade" would be listed. Gilbreth spoke of a "range of time" in which each therblig could be performed.

The first practical attempt to develop predetermined motion time standards was made by A. B. Segur, a consulting engineer, prior to 1930. The results of his researches, however, were made available only to his clients so that his system of "motion time analysis" was imperfectly understood by the industrial engineering profession and its applications were limited. At the same time, the procedure when applied by properly trained engineers met with considerable success and helped to focus attention on the value of the predetermined motion time standard approach.

A somewhat similar procedure was developed by three industrial engineers of the Radio Corporation of America. An article by these three, "Motion Time Standards," by J. H. Quick, W. J. Shea, and R. E. Koehler, which appeared in the magazine, *Factory Management and Maintenance*, in 1945, gave a partial description of their procedure which they called the "Work Factor System." One of the major advantages which they pointed out for their system was that it eliminated the use of the stop watch in determining the time required to do manual work.

A third development in the field of predetermined motion time standards came as the direct result of seeking a solution to the human relations problem mentioned above. At the suggestion of the author, the Westinghouse Electric Corporation sponsored a study beginning in 1940 which led to the development of what is now called the "methods-time measurement procedure" or MTM. It was thought at first that it might be possible to develop a "methods formula" for various classes of work which would make it possible to establish an effective method without having to study an existing job. Accordingly an intensive study was made of sensitive drill-press work. When motion time data were at length compiled, it was found that they applied not only to sensitive drill-press work but to manual work of all kinds, because the same motions were used, as Gilbreth originally pointed out, "in varying combinations and sequence" throughout industry. The research was based on the therblig breakdown of micromotion study, although it was found necessary to redefine several of the basic elements in order to permit the exact measurement of time.

The procedure after several years of careful testing was described for the benefit of the industrial engineering profession in the book *Methods-Time Measurement* by Maynard, Stegemerten, and Schwab published in 1948. It attracted almost immediate attention because the need for such a procedure had long been clearly recognized. The magazine *Fortune* in its October 1949 issue published an article entitled

"Timing a Fair Day's Work" which gave a popular explanation of the MTM procedure. The tables of predetermined motion time standards which they published to show how the procedure works are reproduced here as Fig. 2.

Industrial Engineering and the Worker.—

From the very beginning, industrial workers took a keen interest in industrial engineering because it influenced nearly every phase of their industrial lives. The industrial engineer designed the methods and motion patterns they had to follow to do their work successfully. He trained them to use these methods or at least saw that they were properly trained. He influenced the conditions under which the work was done. He established the time which was allowed for doing the work and established the allowances given for rest, delays, and personal necessities. Finally he often influenced the amount which the worker earned through job evaluation and the application of wage incentives.

Since both industrial engineers and workers are human beings, it was inevitable that there would be a variety of relationships and attitudes among them ranging from complete distrust and hostility to full confidence and respect for one another's viewpoints. Thus it is impossible to say that "labor's attitude is thus and so" and have it be universally true. There has been a variety of attitudes from the beginning, some justified and some unjustified.

Speaking in terms of trends and recognizing that there are always many, many exceptions, it is probably safe to say that the early reactions of the workers to industrial engineering and scientific management were largely emotional. In spite of Taylor's assurances that scientific management resulted in a new emphasis on the importance of the individual workman, there was a tendency to fear it as a device which would reduce the worker to the status of a robot. The stop watch was looked upon as an inhuman mechanism designed to force workers to work at a pace which would quickly wear them out. This emotional attitude which was reflected in much of the management literature prior to 1920 finally caused the Congress of the United States of America to write into its appropriations bills for the Army and Navy in 1915 a clause prohibiting the use of the stop watch and the use of incentives in any Army or Navy installation. This ban persisted for 36 years.

It must be recognized that there was a certain justification for a distrust of industrial engineering. Inept or unscrupulous managements had demonstrated all too clearly that the stop watch could be used to the detriment of the worker. In a few instances, time studies were made secretly, standards were carelessly and inaccurately set, rates were cut when earnings reached a certain level, and the workers were unreasonably speeded up. The malpractices of a few managements damaged the reputation of industrial engineering out of all proportion to their numerical importance.

In addition, the period during and immediately following World War I witnessed the mushrooming into prominence of a number of self-styled "efficiency experts." Among them were a number of unqualified, untrained, unethical individuals who by misapplying a technique which they did not understand did much to damage the name of industrial engineering and to retard its application.

During the early part of the 1920's, industrial engineers had to win back the ground which had been lost. This was accomplished by sound, relatively unspectacular work on the part of a number of technicians, who, convinced of the beneficial results which the procedure, properly applied would bring, pressed for its application at every opportunity. This led to a period of fairly smooth sailing from 1925 to 1930. Management increasingly began to give industrial engineering a permanent place in the organization. In the growing prosperity of the late 1920's, few people questioned the wisdom of technological change. Unorganized labor in fact accepted it as a part of the normal development which was carrying the United States to an undreamed of level of material prosperity. The workers insisted that industrial engineering should be applied fairly and competently, but they raised little objection to any sound work which the industrial engineer wished to do.

In 1930, attitudes began to change again. The growing depression brought fears of unemployment. Suddenly security came to be the thing to be desired above all others. Instead of higher earnings—the factor which had gained acceptance for wage incentives up to that time—steady earnings seemed more important. With only a limited amount of work to be done, many workers began to feel that instead of doing it more quickly, making higher earnings temporarily, and then getting laid off, it was better to do the work more slowly so that it would last longer.

Shortly after 1933 under the encouragement given by the National Industrial Relations Act, unions began to grow in size and strength. In order to attract new members, it became expedient to attack management's activities, to produce grievances, real or imagined, and to promise the workers an immediate improvement in their lot if they would join the union. Industrial engineering lent itself well to attacks inspired by political considerations, and the popular union attitude was to oppose industrial engineering and related practices.

Management's answer to this was to attempt to "educate" its workers with respect to the purposes and fairness of industrial engineering. Courses in work simplification, time and motion study, and the like were held in which the participation of union representatives was invited. This trend fitted in well with labor's desire to have a greater say in the affairs of management. As they learned more about industrial engineering, they asked to have a part in the establishing of standards. They took a keen interest in all matters pertaining to wage incentives and began to have a great deal to say about plans currently in effect and new plans proposed by management. During World War II when wages were controlled by the government, the War Production Board insisted on approving all new wage incentive plans. Before it would consider a new plan, an application for approval had to be submitted jointly signed by both management and the union if a union was involved.

Thus the trend toward the participation of the workers in industrial engineering matters continued. As it developed, the acceptance of the procedure as desirable from both a social and an economic viewpoint grew. When after World War II groups of management and labor people from European countries began to visit the United States under the auspices of the Marshall Plan's

Economic Cooperation Administration, union leaders helped management point out to the visitors the manner in which productivity is increased by industrial engineering. By 1952 when the tempo of the drive for increased productivity in Europe was stepped up by the Mutual Security Agency, successor to ECA, American labor representatives took a leading part in persuading the free labor unions of Europe to accept under certain safeguards sound industrial engineering practices.

Development of Industrial Engineering Techniques.—This keen interest on the part of labor in industrial engineering forced the constant improvement of industrial engineering procedures. For example, the most controversial step in the time study procedure is the one which involves "performance rating." The object of time study is to develop a time standard for doing a specified task which can be met by a qualified operator giving an average or normal performance. If the operator who is being time studied is working at the normal performance level, this is a simple matter. The time obtained from the study is the normal performance time and hence is the desired standard. But when the operator works at a pace which is slower or faster than normal performance, it is necessary to adjust the time values determined by time study to the normal level.

There have been a number of methods used for doing this. The earliest methods were purely mathematical. They called for adjusting the raw time study data by a series of elaborate computations until finally a calculated standard was obtained. The processes were impressive to those who are impressed by slide rules and mathematical computations, but they were for the most part meaningless as industrial engineers soon began to realize. The best of the mathematical procedures were based on the assumption that skilled operators performed each cycle of a repetitive operation in exactly the same time—or in other words were consistent in their performance times—which even casual observation showed was by no means the case. Other mathematical procedures did not have even this much logic behind them. They were all eventually discarded by industrial engineers in favor of procedures which require the time study observer to judge how well or how poorly the operator is working—known as performance rating.

Because performance rating is a subjective procedure involving the element of judgment, it often became a matter of controversy. An industrial engineer could sincerely believe that an operator was giving a below normal performance during a study and would rate him accordingly. The operator with equal sincerity could believe that he was giving a better than normal performance. There was no easy way of resolving this difference of opinion. Other people such as the foreman and the union steward could be called in to check the opinions of the industrial engineer and the operator, but since they too had to rely on the factor of judgment, they were as likely to add to the controversy as to arrive at a satisfactory answer.

The two methods of performance rating which have been most widely used are called "leveling" and "effort rating." Industrial engineers have worked constantly on the refinement of these procedures in an attempt to make them more objective and less controversial.

The leveling method of performance rating was developed in 1925 by Lowry, Maynard, and Stegemerten as an outgrowth of the book they were writing at that time on time and motion study. None of the then existing methods of arriving at standards representing average or normal performance seemed satisfactory to them when they attempted to describe them in their book. Therefore, they set aside their writing for a year and conducted a research study on performance rating.

The first step was to establish criteria for judging performance. The factors which were chosen after study and analysis as affecting performance most importantly were skill—or proficiency at following a given method; effort—or will to work; conditions—i.e., working conditions; and consistency. Skill and effort were seen to have the greatest effect. The range of useful skill and effort was divided into six classes: poor, fair, average, good, excellent, and super skill; and poor, fair, average, good, excellent, and excessive effort.

Each degree of skill and effort was next carefully defined. Average performance was considered to be the equivalent of the fair day's work which is to be received in exchange for a fair day's pay. It represented the effort level which could easily be maintained year in and year out by the physically normal operator without in any way requiring him to draw upon his reserves of energy. It was a pace which appeared somewhat slow when observed and which could be accelerated without too much difficulty under the encouragement of a wage incentive plan.

The operator considered to be giving an average performance with respect to skill was one qualified to do the job who had been at the work long enough to do it without undue hesitation, planning, or errors. He was not noticeably good at doing the job, but neither was he noticeably poor.

When all skill and effort levels had been carefully defined, the cooperation of approximately 175 time study engineers was obtained to determine by actual observation how much time was increased or decreased by performances below and above average. After a year of collecting data, the table shown by Fig. 3 was developed. The "leveling factors" added to 1.00 result in a multiplier which was used to adjust time data obtained during time study to the average performance level.

The effort rating procedure as it is most commonly used rates performance by judging speed of motions. The observed speed is compared with a mental concept of normal speed, and an adjustment factor is arrived at accordingly. If the observer believes that the operator is working 25 per cent faster than the normal pace, he multiplies the time data obtained from a time study of that operator by 1.25 to arrive at the normal time for doing the work.

Both of these procedures and the several variations which stem from them which have been used by industrial engineers required the use of judgment in rating observed performance. In order to improve the consistency with which industrial engineers rated performance, the Society for the Advancement of Management in 1943 set up a Committee on the Rating of Time Studies to study the problem of performance rating and to determine what could be done to improve existing procedures. The committee decided that

Skill			Effort		
+ 0.15 + 0.13	A1 A2	Superskill	+ 0.13 + 0.12	A1 A2	Excessive
+ 0.11 + 0.08	B1 B2		+ 0.10 + 0.08	B1 B2	Excellent
+ 0.06 + 0.03	C1 C2	Good	+ 0.05 + 0.02	C1 C2	Good
0.00	D	Average	0.00	D	Average
− 0.05 − 0.10	E1 E2	Fair	− 0.04 − 0.08	E1 E2	Fair
− 0.16 − 0.22	F1 F2		− 0.12 − 0.17	F1 F2	
Conditions			Consistency		
+ 0.06	A	Ideal	+ 0.04	A	Perfect
+ 0.04	B	Excellent	+ 0.03	B	Excellent
+ 0.02	C	Good	+ 0.01	C	Good
0.00	D	Average	0.00	D	Average
− 0.03	E	Fair	− 0.02	E	Fair
− 0.07	F	Poor	− 0.04	F	Poor

FIG. 3. Leveling factors for performance rating.

rather than attempting to develop a new procedure, it could perform the greatest service by developing a set of standards against which any industrial engineer could check his own concept of normal and determine in general how he was rating performance in comparison with other industrial engineers.

Aided financially by industrial companies who appreciated the seriousness of the performance rating problem, the committee prepared a number of motion pictures of people working at various performance levels. They had these motion pictures rated under carefully controlled conditions by over 1,200 experienced time study engineers. Statistical treatment of the resulting data provided a series of bench marks against which any individual engineer could check his own concepts of performance levels. The motion picture films were made available for purchase by industrial companies to be used for training purposes. They proved to be an aid in improving the consistency with which a group of engineers judged performance and were used with good effect in developing a common concept of normal performance among industrial engineers, supervisors, and operators.

The effort to improve and refine industrial engineering techniques was by no means confined to the United States. In the field of performance rating, for example, important studies were made and reported upon in 1950 by engineers in Switzerland and France. In the field of predetermined motion time standards—where incidentally the problem of performance rating is largely eliminated—although the major developments came out of the United States, important contributions to the general fund of knowledge about motions and motion times were made in England, France, Holland, and Germany.

The fact that industrial engineering is used throughout the world presents a continuing problem in international standardization. Problems in terminology became so serious, for example, that in 1950 the International Committee on Scientific Management, CIOS, set up a subcommittee on the Standardization of Management

Terminology to begin work on eliminating what had been called "Management's Tower of Babel."

In the United States, similar activities were undertaken to bring a better degree of standardization and understanding to the industrial engineering field. The terminology project of the Work Standardization Committee of the American Society of Mechanical Engineers (ASME) has already been mentioned. This same society in 1941 established a Committee for the Standardization of Therbligs, Process Charts, and Their Symbols. Some idea of the difficulties of bringing about standardization in a vigorous and rapidly expanding field like industrial engineering may be gained from the fact that this committee worked six years, held innumerable meetings, and carried on lengthy correspondence with numerous industrial engineering authorities in the United States and Canada before it felt ready in 1947 to publish its first ASME Standard on *Operation and Flow Process Charts*.

Such activities, however, difficult as they are, have helped to develop the "universal language" which is so essential in scientific fields. The first page of the ASME Standard on *Operation and Flow Process Charts* illustrates how clear definitions and standardized symbols and terminology have sharpened this particular tool of industrial engineering. It reads as follows:

SECTION 1 PROCESS CHART

DEFINITIONS

1. *Process Chart*. A process chart is a graphic representation of events and information pertaining thereto occurring during a series of actions or operations.
2. *Operation Process Chart*. An operation process chart is a graphic representation of the points at which materials are introduced into the process and of the sequence of inspections and all operations except those involved in material handling. It includes information considered desirable for analysis such as time required and location.
3. *Flow Process Chart*. A flow process chart is a graphic representation of the sequence of all operations, transportations, inspections, delays, and storages occurring during a process or procedure, and includes information considered desirable for analysis such as time required and distance moved.
 - (a) The material type presents the process in terms of the events which occur to the material.
 - (b) The man type presents the process in terms of the activities of the man.

PROCESS CHARTING PROCEDURE

4. For analytical purposes and to aid in detecting and eliminating inefficiencies, it is convenient to classify the actions which occur during a given process into five classifications. These are known as operations, transportations, inspections, delays, and storages. The following definitions cover the meaning of these classifications under the majority of conditions which will be encountered in process charting work.

ACTIVITIES DEFINED

5. *Operation*. An operation occurs when an object is intentionally changed in any of its physical or chemical

characteristics, is assembled or disassembled from another object, or is arranged or prepared for another operation, transportation, inspection, or storage. An operation also occurs when information is given or received or when planning or calculating takes place.

6. *Transportation*. A transportation occurs when an object is moved from one place to another, except when such movements are a part of the operation or are caused by the operator at the work station during an operation or an inspection.

7. *Inspection*. An inspection occurs when an object is examined for identification or is verified for quality or quantity in any of its characteristics.

8. *Delay*. A delay occurs to an object when conditions, except those which intentionally change the physical or chemical characteristics of the object, do not permit or require immediate performance of the next planned action.

9. *Storage*. A storage occurs when an object is kept and protected against unauthorized removal, shown by inverted triangle.

10. *Combined Activity*. When it is desired to show activities performed either concurrently or by the same operator at the same work station, the symbols for those activities are combined, as shown by the circle placed within the square to represent a combined operation and inspection.

11. When unusual situations outside the range of the definitions are encountered, the intent of the definitions summarized in the following tabulation will enable the analyst to make the proper classifications.

Classification	Predominant Result
Operation	Produces or Accomplishes
Transportation	Moves
Inspection	Verifies
Delay	Interferes
Storage	Keeps

Wage Incentive Plans.—Frequent mention has been made of wage incentive plans because they have been an important part of industrial engineering activities since the time of Taylor. A review of the way in which wage incentive philosophies altered between 1900 and 1950 will help in understanding more clearly the changing, growing character of industrial engineering.

The period between 1900 and 1930 saw the reputation of industrial engineering sink to a low level as the result of rate cutting, the fumblyings of the so-called "efficiency experts," and a variety of questionable practices on the part of some managements. It rose again as sound practitioners quietly demonstrated that industrial engineer-

ing properly applied could benefit everyone. The wage incentive installations of this period all had one feature in common. They were made largely as the result of unilateral decisions. If management decided to install an incentive plan, it selected the plan, established the standards, and started the plan in action at the time which best suited its own convenience. True, the more advanced managements endeavored to "sell" the plan to the workers, but the product was largely management's product designed without benefit of market research to see what the customer—that is, the worker—really wanted.

In doing the selling, the principal benefit which was offered was increased earnings. This fitted the philosophy of the times quite well. Rugged individualism was popular and everyone was interested in making more money for himself. So the money benefit was accepted, and the incentive which it provided caused the workers to pitch in and make even a poorly conceived wage incentive plan work reasonably well.

The depression of the 1930's intervened to make security seem more important than higher individual earnings. This period did not last long, but it had a profound effect on those who lived through it. Management's attitudes were shaped by the 1920's. They wanted to continue to make unilateral installations; they continued to rely on the appeal to the desire of the individual to make higher earnings in selling wage incentives to the workers. But the workers had changed their minds about the rightness of high individual earnings. They were even at that moment not quite sure that high productivity in general was socially desirable. So the stage was set for trouble as the unions began to grow, with enough tensions on both sides to cause many, many difficulties.

To overcome these difficulties, different solutions were tried. One which attracted a great deal of attention from 1934 to 1938 was in the automobile industry where the attempt was made to overcome the problems caused by direct incentives by going to measured day work. At the beginning of the change-over, the workers agreed that if they were paid the average earned rate they had received in the past they would continue to maintain their same output. They even agreed that the worker who did not keep up could be discharged. To management, this seemed to be the solution to many problems. Inconsistencies in earnings would immediately be eliminated. Because earnings were not tied directly to a standard, it was felt that the pressure would be taken off the industrial engineer and management for complete accuracy and that a better human relations situation would result.

But it did not work out that way. Human nature being what it is, little by little performance deteriorated. The burden of proof as to whether a given performance was acceptable was on management, and it became increasingly difficult to enforce high effort by disciplinary measures. The net result of measured day work, therefore, was a performance level which gradually fell toward the unmeasured day work level. Companies which were able to evaluate the results reported that production fell off by at least 25 per cent.

In spite of all of the problems involved, many companies continued to use and expand their use of wage incentives all through the difficult 1930's. They paid an increasing amount of attention to

method, they strove for greater accuracy in setting standards, they gave guarantees which eliminated certain abuses of the past, and more and more they consulted with their workers on wage incentive problems, either voluntarily or as the result of union pressure. They demonstrated that wage incentives, properly and intelligently administered, still brought good results, and they paved the way for the next development which came at the beginning of World War II.

At that point, the need for greater production suddenly became apparent to nearly everyone. The make-work and slow-down attitudes born of the depression did not die immediately, but they were more or less pushed into the background for the duration. The War Production Board, desperate for more and more production, strongly advocated the use of wage incentives under certain conditions. The conditions were drawn up by men who understood wage incentive problems and served to create an understanding of sound wage incentive practices among a much larger segment of the industrial population than before.

As has been pointed out, in order to get approval for a new incentive plan, it was necessary to submit an application to the War Production Board signed by both management and the union if a union was involved. This meant that management could no longer take unilateral action. It was necessary to consult with the union about every detail of a proposed plan before the union would agree to go along. The industrial engineer was forced to develop his plans much more thoroughly than before; make accurate appraisals of the effect of the plan on production, earnings, and working conditions; and then by effective selling techniques in which the interests of the prospect were put above the interests of the salesman gain acceptance for his proposed course of action.

These wartime experiences helped to develop the industrial engineer to a state of greater effectiveness in the postwar period. He came to recognize clearly that his wage incentive plan had to be tailored to the needs and basic beliefs of the group who were to work on it. He had to become a human engineer as well as a technical engineer. But the net result was good. In addition to becoming a broader, more understanding man himself, his installations tended to receive greater acceptance from the workers. A big step forward toward more mature relations between workers and the industrial engineer had been taken.

Application of Industrial Engineering.—Industrial engineering procedures were first applied largely to highly repetitive work. It was entirely obvious that if a large number of identical parts had to be manufactured, it would pay to study and improve the methods by which they were produced, establish time standards, and introduce a wage incentive plan which would encourage high production through the payment of high earnings.

The early installations on highly repetitive work were so successful, however, that both management and the workers wanted them extended to less repetitive work. Management wanted the cost reductions which such installations bring. The workers on less repetitive work, seeing the higher earnings of those on the repetitive jobs, asked for the same opportunities to increase their pay.

For the industrial engineer, this situation

offered both an opportunity and a challenge. It offered an opportunity to extend the field of his service. At the same time, it presented a challenge to find better and quicker methods of doing his own work so that it would be economically justified. On low quantity work where only a few of a given part were produced, it obviously would be impractical to time study each operation in detail. The work would be completed long before the time studies could be worked up and the standards computed.

The solution to this problem was found in the development of standard data or time formulas. These are compilations of time study data obtained by time studying representative jobs in a given class of work, arranged so that they can be used for establishing standards for similar jobs which have not been time studied. Time formulas reduce the time required to establish a standard. The time required to make and work up a time study on repetitive work is commonly from 1 to 4 hours where the length of the operation cycle is fairly short, and may be much longer on larger work where one operation cycle may run as high as 100 hours. The time required to establish a standard from a time formula will in most cases range from 1 to 15 minutes.

The formula approach was suggested by Taylor, but industry was somewhat slow to use it. There were two reasons for this. On many classes of work, the derivation of a time formula is a fairly complex task. It is not easy for one who has no training in time formula work to understand how it is possible to develop a formula which will permit the establishing of accurate and consistent standards on an irregular activity such as, say, storeroom work. Therefore management was slow to authorize time formula derivation activities. The second obstacle was the length of time required to develop the time formula which on the average was about three months. It required considerable patience on the part of management and workers alike to wait while the engineer went through what seemed to be an endless series of studies and computations before the first standard could be set and incentive payment begun.

In spite of these obstacles, however, the use of standard data and time formulas spread, and standards and wage incentives were introduced on less and less repetitive work. With the coming of predetermined motion time standards, the time required to develop a time formula was sharply reduced, sometimes to as little as two weeks. This gave further impetus to the use of formulas. Applications spread from low quantity production work to such indirect labor operations as tool making, maintenance work, shipping and receiving, janitor work, and the like. The benefits to be derived from industrial engineering were found to be just as substantial on indirect labor operations as on direct labor operations.

Although industrial engineering has always been most widely used in factory work, it has been used for office work as well. It has also been applied with good results to distribution activities, particularly by the oil industry. Outside industry, industrial engineering applications have been made to all manner of activities where human labor is involved—in hospitals, homes, libraries, wholesale and retail establishments, and the like. Notable applications to agricultural work have been reported from Sweden, Hawaii, and the United States. By the end of the first

half of the 20th century, it was evident to people in every country and in every walk of life that industrial engineering had much to contribute to the continuing raising of standards of living throughout the world.

HAROLD B. MAYNARD,
President, Methods Engineering Council, Pittsburgh, Pennsylvania.

INDUSTRIAL HOUSING. With the growth of motor transportation and the entrance of government into the field, industrial housing has lost the clear definition it once had, the housing of workers by employers. Today company housing in the older sense is likely to be instituted only in the most isolated areas, for a mine or a new power development.

The term industrial housing is now applied in the United States, by extension, to any housing planned for workers in industry (not necessarily urban), whether by federal or other government agency, employers, or private agencies, with or without the aid of public funds. Such projects are likely to be large apartment or garden apartment structures, rather than the single-family dwellings they usually were in Great Britain during the Industrial Revolution and in the early mill towns of New England, built by the mill owners to attract help to new industries.

Nowadays the tenants pay rents which cover a good deal, if not all, of the expense of construction, maintenance, and financing. The old company housing was often rent free or charged only nominal rents. Under this arrangement the worker occupied the apartment at the discretion of the employer, and often had to waive state and local eviction restrictions as part of the original occupancy agreement. As a result eviction was a powerful weapon in the hands of the employer during industrial strife, and the tent colony was a common feature of large strikes. For this reason, and because many workers resented having the same man or company as both employer and landlord, they sought lodging elsewhere as soon as it became available. Commercial speculative housing, usually in the form of two- or three-story frame railroad or shoe-box flats, detached or semidetached, sprang up everywhere in the United States.

In Europe through the 19th century there was a greater tendency to combined company-government housing corporations, in addition to schemes which encouraged the purchase of company-built housing by employees or the setting up of employee cooperatives for the purpose. The German Krupp firm started a housing program in 1861, which by 1919 housed 12,000 families, making loans to employees. One of the model company towns, including landscaping and recreation facilities, was begun in England in 1895 by the Cadbury chocolate interests.

In the United States the Pullman development, now part of Chicago, while a great improvement

over most company and speculative housing in plan and recreational provisions, included the worst elements of paternalism in its extreme regulation of the lives of residents—forbidding saloons, for example. A more enlightened philanthropic project was that of Nelson Olsen Nelson at Le Claire, near St. Louis. Gary, Ind., founded in 1906, is the most spectacular example of a company town.

Company Town.—Little good has been said by sociologists about the company town. The absence of genuine community organizations, the centralized control of civic functions by direct or indirect employees of the controlling company, the frequent evil of the company store, which encouraged indebtedness and charged higher than prevailing prices, are well-known abuses. Often the police force, schoolteachers, and even the clergy were maintained by the company and were regarded as its instruments.

The development of the automobile, permitting the worker to live some distance from his job, helped break up the direct control of the town by the controlling local industry, although indirect control, as depicted in the sociological study *Midletown* (1929), continues. During World War II the car pool and the trailer camp made it possible to locate new factories in isolated regions without provision for housing all the plant's expected workers.

Early Industrial Housing.—Industrial housing began with the need to provide for workers in the new manufacturing villages which grew up in the 18th century, especially in England, where watercourses supplied power for textile machinery. Often these factories were some distance from established centers of population, and provided both employment and housing, at minimum standards, for former farmers and villagers who had been put off the land by enclosures. The houses, minimal and brutally congested, became one of the blights of the Industrial Revolution, and conditions worsened when coal became the prime motive power, as company housing was huddled close to the factories, with no concern for zoning, or for light and air. In England as late as 1925 about one third of the miners still occupied company houses.

In the United States the mill in Pawtucket, R. I., planned by Samuel Slater in 1790, began a similar process. At first mills only turned raw cotton into yarn, with the weaving performed by farmers in their cottages. After 1815 the complete factory, with all processes under one roof, came into being, and with it the need for company housing. Originally there was a certain community of origin and feeling between employer and employee, with some feeling of mutual responsibility; but as industry grew, and absentee landlordism with it, housing standards fell. Then immigrants from Europe were welcomed to man the machines, first the Irish, then workers from eastern and southern Europe, and the Lawrences of the new era became "pay envelope" cities, as the employer's concern in his employees ceased at the mill gates. The speculative builder moved in; wooden three-deckers took the place of the cottages and the "back alley" became crowded with tiers of flats.

World War I Period in the United States.—During World War I the United States began to catch up to the example of European nations in providing housing for workers in essential industry. One agency, the Emergency Fleet Corpora-

tion, employed government architects and encouraged subsidized company housing. It actually carried some of its projects to the point of having them occupied, and continued operating after the armistice, as ships continued building. Another federal agency, the United States Housing Corporation, started later and curtailed and canceled its projects when the war ended.

An interesting wartime project was the Bayonne Housing Corporation, founded by a group of leading industrialists at a meeting on Oct. 4, 1917, to provide decent housing for oil workers, at moderate but unsubsidized rentals. The first group of houses was completed in 1924-1925, after the New Jersey tenement house law and the local building code had been amended to allow the building of garden apartments. Recognizing that the basic problem of housing was the cost of financing and the desire for quick pay-off of investment, the project was planned for long-term funding. The H-shaped buildings covered only 36 per cent of the site, in conscious contract with other workers' apartments covering 70 to 80 per cent. The Bayonne project was eventually sold to a private entrepreneur.

Modern Industrial Housing.—In World War II the United States government moved more quickly, and many federal projects were put up at shipyards, aircraft factories, and other large plants, and there was useful experimentation in new materials and types of housing, in an attempt to save both time and cost. After the war the role of the government in financing housing by insuring bank investments was one of the foundations of large-scale building.

The devastation of Europe in the war forced much construction into the hands of government agencies, aided by shipments of American materials and equipment. The result was the establishment of standards of space and equipment. In the Communist countries of eastern Europe all housing is, of course, a government function, and great public emphasis was put on the replacement of destroyed housing by workers' apartments.

By their very nature, such enterprises as mining and lumbering, far from inhabited centers, require special housing programs for employees. At first the roughest and most primitive imaginable, such housing improved as the living conditions of workers became part of union contracts. A new development of the isolated project is the housing of American construction workers during the establishment of United States airbases and other installations all over the world, and then of civilian workers at such bases when completed. For example, at the airbase at Goose Bay, Labrador, before a spade could be turned, living quarters had to be established for a construction force of 5,000 men. Besides barracks and mess hall facilities, a movie theater, library, and Hudson Bay store were provided. A more significant development in industrial housing is the epoch-making Kitimat power and aluminum project in British Columbia, Canada. A city for 50,000 people, with homes, shops, and schools, was laid out by Clarence Stein for the Aluminum Company of Canada, in preparation for future workers at a plant built in the wilderness.

A modern variation of the company town is Fairless, Pa., made up of the prefabricated Gunnison houses manufactured by the United States Steel Corporation, and occupied by employees of the company's Morrisville plant. Unlike the classic company town, these houses are occupied

in great part by white-collar workers, and the financial arrangements involve purchasing the dwelling with the assistance of the employer. Apart from such special examples, the company town planned from the start by the employer for his workers is becoming an incident in the past growth of industry.

Architectural Consultant.

INDUSTRIAL HYGIENE. The application of the combined techniques of engineering, chemistry, physics, and medicine to the control of the environment of the industrial worker, in order to protect his health, is the major concept of industrial hygiene. Employment of medical and nursing principles to improve the health of a group of employees, entirely apart from any occupational hazards, is a secondary concept.

Infectious diseases, with a few exceptions, are not typically occupational in origin and are not a major concern of the industrial hygienist. Occupational diseases, prevention of which is the chief purpose of industrial hygiene, are most commonly caused by dusts, fumes, vapors, gases, irritating chemicals, and abnormal physical factors in the environment of the worker.

Dust Diseases.—*Silicosis*, a disease of the lungs caused by inhalation of dust containing free silica, is perhaps the most important occupational disease. The American Public Health Association defines silicosis as a "disease due to breathing air containing silica (SiO_2), characterized anatomically by generalized fibrotic changes and the development of miliary nodulation in both lungs, and clinically by shortness of breath, decreased chest expansion, lessened capacity for work, absence of fever, increased susceptibility to tuberculosis. . ."

Ordinarily silicosis is developed only after several years of work in a dusty environment; but when dust concentrations are unusually high, it may follow exposure of only a year or two. Combined silica (silicate) does not cause silicosis. The form of free silica most commonly encountered in nature and responsible for most cases of this disease is quartz. Occupations in which silicosis may present a hazard include mining, tunneling, stonecutting, pottery manufacturing, sandblasting, and other foundry operations.

Asbestosis is a lung disease caused by inhalation of asbestos fibers. The changes produced are unlike those of silicosis. The fibrosis is diffuse and not nodular, and there is less susceptibility to tuberculosis. However, there is evidence that asbestosis may be associated with lung cancer.

Byssinosis is a lung disease contracted by cotton mill workers, especially in England.

Siderosis is a nondisabling condition characterized by a deposit of iron oxide in the lungs, frequently observed among welders and miners of iron ore.

Berylliosis results from the inhalation of beryllium oxide and certain other beryllium compounds. While its chief symptoms refer to the respiratory tract, it is considered by some authorities to be a systemic disease. The greatest concentration of cases has been in the fluorescent lamp industry, where the phosphors (fluorescent powders) used to coat the inside of the lamps formerly

contained beryllium. Short exposure to high concentrations of beryllium compounds, particularly soluble compounds such as the fluoride, may result in pneumonitis. Both forms of the disease are frequently fatal.

Heavy Metal Poisoning.—*Lead poisoning* ranks next to silicosis among occupational diseases. Formerly it was associated chiefly with the painting trade; now it is rarely encountered among house painters, but is found frequently in such diverse industries as storage-battery manufacturing, nonferrous foundries, lead smelters and refineries, plastics manufacturers, and automobile assembly plants. The commonest symptoms are colic, weakness of the wrists, and anemia.

Mercury intoxication, as observed in industry, usually results from inhalation of the vapor. It was formerly common among felt hat makers, who knew it by the descriptive term, "hatter's shakes." Many countries and various states of the United States ban the use of mercury-treated fur for hat manufacturing; but there are many other industrial uses of mercury.

Manganese poisoning from the inhalation of high concentrations of the dust of manganese compounds may result in damage to the nervous system and partial paralysis. Typical symptoms are a stumbling gait and mask-like facial expression. The disease is most prevalent in smelting and mining operations.

Cadmium poisoning most frequently results from inhalation of fumes of heated cadmium, and takes the form of a severe chemical pneumonitis. Chronic cadmium poisoning among workers engaged in the manufacture of cadmium-nickel storage batteries has been reported in Sweden and France.

Zinc fume fever is a transient illness resulting from inhalation of freshly formed fumes of zinc oxide. It occurs chiefly among brass founders and welders of galvanized metal.

Other heavy metals, such as arsenic, vanadium, thallium, and uranium, are toxic and produce occasional occupational intoxications.

Organic Solvents.—*Benzene*, or benzol, is one of the most dangerous of the common solvents. Absorption of the vapor not infrequently results in blood changes which may progress to aplastic anemia, a fatal disease. Because of its toxicity, the use of benzene in rubber cements and lacquer formulations has been virtually abandoned in the United States; but it is still employed in paint removers and as a raw material in the chemical industry.

Carbon tetrachloride, widely used as a cleaner because it is volatile and will not burn, is a dangerous kidney and liver poison. At present it is probably the number-one toxic solvent problem in the United States.

Carbon disulphide was formerly used in the rubber industry, but is now found chiefly as a raw material in viscose rayon manufacture. It produces mental symptoms, leading in extreme cases to insanity. Major episodes of carbon disulphide poisoning have been reported in Poland and Italy.

Other solvents which have produced serious occupational intoxications include tetrachlorethane, ethylene chlorohydrin, and dioxane.

Pesticides.—The use of toxic chemicals to control insect, fungus, and rodent pests has created some serious occupational hazards. Methyl bromide, a gas used as a fumigant, also to some extent as a fire extinguisher, damages the central nervous system and also is a lung irritant. Parathion,

one of the most effective insecticides known, has proved to be extremely dangerous to handle. DDT, on the other hand, has not proved especially hazardous to workers.

Occupational Cancers.—The hydrocarbons present in coal tar, and in some oils derived from petroleum, are markedly carcinogenic, at least to the skin. Cancer of the scrotum was formerly a not uncommon affliction among chimney sweeps in England. Mule spinners in that country frequently contracted the same condition by contact with lubricating oil. Tumors of the bladder, found in abnormal frequency among workers in dye plants, have been traced to betanaphthylamine and benzidine. Aniline, which was formerly blamed, has been shown not to cause this disease. A high incidence of lung cancer has been observed among workers in plants manufacturing chromates. The exact compound responsible has not been definitely determined. So far there have been no similar reports from other industries in which chromium compounds are used. Arsenic compounds have been reported to cause cancer of the skin and also of the respiratory organs.

Radioactive substances are among the most dangerous carcinogenic agents. A very high death rate from cancer of the lung has been observed in uranium mines in Czechoslovakia where high concentrations of radon were present in the air. Tumors of the bone developed in many workers who used radioactive luminous paints without proper precautions. These individuals had absorbed radium, which was deposited in the bones.

Skin Diseases.—Dermatoses, or diseases of the skin, are the commonest of occupational diseases. The most frequent causes are solvents, oils, and alkalis. Substances whose use is frequently associated with outbreaks of dermatitis include chromates, *p*-phenylene diamine, and hexamethylene tetramine.

Infectious Diseases.—A few of the infectious diseases are frequently occupational in origin, such as anthrax (wool sorters and tanners), Weil's disease (fish handlers, sewer workers), and brucellosis (slaughter-house employees).

Illness from Physical Conditions.—Physical conditions which may bring on occupational illness include excessive temperatures (heat stroke), high atmospheric pressures (bends), ultraviolet and infrared radiation (eye injury and skin burns), and X-rays and radiation from radioactive sources. The latter may cause blood changes, skin burns, blindness, and, as noted above, cancer.

TESTING AND CONTROL

Air Analyses.—The essence of industrial hygiene is the measurement of harmful conditions, particularly the concentration of dusts, fumes, gases, or vapors in the workroom atmosphere.

Mineral dusts are determined by a counting procedure. Ordinarily only the particles below a certain size (5 to 10 microns in diameter) are considered significant. In the United States an impinger containing water or alcohol is commonly employed for collecting dusts. A small amount of the suspension is placed in a shallow cell and the number of particles counted under a microscope. Frequently a light-field setup is used. In England the dust is usually collected dry in a thermal precipitator. In South Africa a konometer, a dry impingement device with a built-in microscope, is widely employed.

Dust concentrations are expressed as numbers of particles per cubic centimeter of air or as

millions of particles per cubic foot of air. Concentrations will range from less than a million particles per cubic foot in air that is relatively free from dust, to several hundred million in highly dusty operations.

Toxic dusts and fumes, such as those from lead, cadmium, and manganese, are usually determined chemically. They may be collected by means of the impinger, with a portable electric precipitator, or on a filter paper. Concentrations are expressed in milligrams per cubic meter of air, and micro-methods of analysis are usually necessary to determine the small amounts of substance present.

Vapors can be adsorbed on activated charcoal or silica gel, and then determined by chemical or physical methods. Flammable vapors can be measured directly by means of a portable detector. Instruments are also available for the direct determination of chlorinated hydrocarbon vapors, and the portable interferometer can be used for the field estimation of many vapors.

Gases are usually absorbed by bubbling the air through a suitable chemical reagent. However, direct chemical testing devices are available for certain gases and vapors in the air, such as carbon monoxide, hydrogen sulphide, benzene, and sulphur dioxide.

Biochemical Tests.—Analysis of urine or blood for toxic substances is an alternative method of measuring exposure. Urinalyses are useful for such heavy metals as lead, mercury, and uranium. The ratio of inorganic to total sulphates (urine sulphate test) is affected by absorption of benzene. The blood contents of lead and of carbon monoxide (carboxyhemoglobin) are useful indices of exposure to these substances. The radon content of expired air is a measure of the radium stored in the body.

Tests to indicate early damage to the body or changes which precede measurable damage are also employed. Examples are chest X-rays to detect early stages of silicosis, asbestosis, and other occupational lung diseases; measurements of methemoglobin in the blood to determine effects of nitrobenzene and allied substances; tests of the cholinesterase activity of the blood, which are a delicate index of absorption of the organic phosphate insecticides, such as parathion. Coproporphyrin in urine is a sensitive test for very early stages of lead poisoning.

Control Measures.—Pre-employment and periodic medical examinations are advisable for workers in occupations in which harmful dusts, fumes, or radiations are present. Individuals with a predisposition to the disease caused by a given agent should avoid an occupation in which it is present in sufficient concentration to produce a hazard. Removal of workers from hazardous exposures at the first sign of illness may prevent the disease from becoming serious. This phase of industrial hygiene often finds the medical profession and organized labor in conflict, since transfer of a worker from a hazardous occupation in which he is skilled to a safer occupation may involve economic hardship.

When a health hazard is shown to be present, by air tests, bio-assay, or other procedures, reduction or elimination of the exposure is indicated. The chief methods of achieving this end are as follows:

(1) Substitution of a less toxic material. Examples: use of steel shot for sandblasting in place of sand (quartz); substitution of naphtha for benzene in rubber cements.

(2) Isolation: enclosure of process to prevent dissemination of dust or vapor into workroom air.

(3) Wet methods: especially where dust is produced; notably effective in underground drilling.

(4) Local exhaust ventilation: removal of dust or fume as it escapes from the process, before it has a chance to be dispersed into room air.

(5) General ventilation: dilution of the air in the room with fresh air to reduce the concentration of atmospheric contaminant.

(6) Personal protection devices: respirators, gas masks, or air-supplied hoods or helmets, where the hazard is a dust or fume; gloves, aprons, or other protection where contact with a corrosive or irritating chemical is the problem.

As a rule, substitution of a relatively non-toxic substance is the most satisfactory solution, and use of respirator devices least satisfactory. Local exhaust ventilation is the solution most frequently applied.

INDUSTRIAL INSURANCE. See LIFE INSURANCE—5. *Types of Insurance and Policies.*

INDUSTRIAL OR LABOR RELATIONS IN THE UNITED STATES. Industrial relations usually means the relationships between employer and wage worker which, with the rise of the factory system, large-scale modern industry, and the corporation after the Civil War, succeeded historically earlier relationships between master and servant and owner-manager and his few employees. The term is applied primarily to relations between management and labor in the manufacturing, extractive, transportation, communications, and distributive industries. In accordance with this usage, employer-employee relationships in other fields are commonly called labor relations; but the distinction is haphazard, for the two terms are also used interchangeably.

Considered in its more restricted meaning, "industrial relations" nevertheless includes a vast complex of diverse, varying, interacting, and interpenetrating relationships. Among essential aspects of industrial relations are wages and hours; labor and social legislation; vocational training; scientific management; inter-racial relationships; collective bargaining; the scope and power of employer organizations and combinations; the strength and status of trade unionism and the influence of the labor movement; labor-management disputes, and voluntary arbitration and government mediation and conciliation; strikes, the status of civil liberty, intervention by the state, and government seizure and operation of privately owned industry; and management

and labor representation in government economic and industrial administrative bodies.

A Modus Vivendi Between Capital and Labor.—In their totality, these relations signify a *modus vivendi* between capital and labor whereby the production and distribution of goods and services are carried on under increasing governmental regulation. But it is a dynamic equilibrium which is the result of a long period of development and which, moreover, is in process of continual change.

The complex character of contemporary industrial relations stands in sharp contrast to the comparatively simple relationship which obtained between employers and employees during the early stages of the industrialization of the United States in the latter part of the 19th century. Basically, that relationship was an unwritten express or implied contract between the employer, who was increasingly a corporation, regarded at law as a juristic person, and the employee, who was invariably an individual. Payment of wages by the employer for work performed by the employee were the principal terms of the contract. Theoretically, employer and employee were equal parties, free to bargain for terms, and acquired equal rights and duties. Actually, however, the employer, because of superior economic strength over the individual employee—whose only marketable asset was his ability to work and who had no alternative but to work—possessed decisive bargaining advantages and dictated the terms of the contract, subject only to the loose and variable control of the competitive system. Owing to the relatively elementary state of industrial development, the rules governing work, formulated by the employer, were correspondingly simple.

Scientific Management.—Three basic factors profoundly modified the development of industrial relations to their present state. The first was the rapid technological revolution which made United States industry the most productive in the world. The development of vast enterprises employing first thousands, then tens of thousands, and, finally, hundreds of thousands of workers, made necessary complex codes of rules governing working conditions. Precision and smoothness are vital in the operation of mass-production industries. Economies made through division of labor and specialization are jeopardized by interruptions to the flow of work arising from absenteeism, tardiness, lack of discipline, and lack of efficient coordination on the part of management.

From these needs arose the theory and practice of scientific management. Originally, scientific management was limited in its basic aim to the achievement of increased productivity through improvement in the skill of the labor force and in the planning and coordinated operation of production. Subsequently, scientific management was extended to include the development of co-operation between capital and labor through cultivation of good will of both parties toward each other. Included in this sphere are establishment of fair standards of work; determination of appropriate, as well as effective, incentives for work; selection of personnel in accordance with the aptitude of workers for various positions and tasks; and a degree of cooperation between management and workers in the practical solution of these problems. Involved in this extension of scientific management are the application to in-

dustrial relationships of the principles of psychology and, in later years, of some tenets of psychiatric science. A further and important development of scientific management has been the cultivation, through public relations, of good will on the part of communities and consumers, both as an advantageous aid in the sale of products and services and as a practical application of a sense of social responsibility toward the public.

Trade Unionism.—The second factor in shaping the evolution of industrial relations was the development of the trade-union movement. For the arbitrary determination by the employer of the terms of the labor contract, the workers sought to substitute collective agreements between employers and workers organized in unions. Thereby labor expressed its desire for a higher standard of living and an improved status in United States society. And it sought to apply to industry the elementary principles of traditional American political democracy.

Its first efforts were confined to wages, hours, and measures to protect health and life while at work. These are still basic considerations in collective agreements, but they are now far from being the exclusive considerations. Gradually, as unions grew in size, strength, and influence and came to be accepted as socially necessary institutions performing valuable functions, the scope of labor's role increased and was reflected in collective agreements, which included, in addition to provisions relating to wages and hours, terms concerning sickness and death benefits, pensions, vacations, methods of employment, limitations on management's right to discharge workers, rules regulating work, and other matters.

Labor and Social Legislation.—Simultaneously, labor demanded of the state that it curb industrial autocracy and further the purposes of labor by the establishment of minimal standards, the provision of various benefits designed to afford workers a measure of security against the uncertainties inherent in the modern industrial system, and the creation of specific labor rights and immunities. Through collective agreements and legislative enactments, the powers and rights of management were limited and the position of labor improved.

Labor-Management Cooperation.—Although unions had been recognized by the courts since the 1840's as lawful combinations, their legal status was long undefined by statute and they had no standing before the courts as parties in suits over the enforcement of contracts. They were strongly resisted by employers. The history of this phase of labor relations is in large part a record of conflict which frequently culminated in violence and often in bloodshed. With the passage of time, however, management learned to accept unionism as a permanent feature of industrial relations and to cooperate with it; while organized labor, once established and relatively secure in its acceptance, tended, for its part, to demonstrate a sober sense of responsibility with respect to its obligations to management and the preservation and enhancement of the national economy. Progressively greater emphasis was placed by both sides on conciliation and arbitration than on lockouts and strikes as means of solving disputes, and some industries in which conflict had been frequent, experienced as much as a quarter of a century of industrial peace.

The Government in Industrial Relations.—A profound change in the rôle of government

was the third basic factor in determining the course of industrial relations. In the prevailing views and attitudes of the latter part of the 19th, and the early years of the 20th, century, the regulation of industrial relations, as of economic relationships generally, was excluded from the functions of government. The regulation of industrial relations was held to be the concern of industry and labor. Only when they dramatically affected the public interest, as in the serious disturbance of public order in large-scale strike violence, were industrial relations considered a proper concern of government.

However, as the growing economy of the United States became increasingly complex, and vast corporate enterprises, in pursuit of their private interests, vitally affected the public welfare, the need for regulation of economic processes by the government became pressing. Participation by the government in industrial relations, following the economic crisis of 1929, formed an important part of the measures undertaken by the federal government under President Franklin D. Roosevelt to cope with the depression.

The essential features of the new policy with respect to industrial relations, which was intended to promote industrial peace, were statutory affirmation of the right of labor to organize, to bargain collectively, and to strike; prohibition of interference with these rights on the part of employers; and establishment of agencies for the mediation, conciliation, arbitration, and administrative disposition of disputes between management and labor. Sweeping regulatory powers over economic relationships, including industrial relations, were vested in the president during World War II. After the war, governmental participation in industrial relations was extended by Congress. By the terms of the Labor Management Relations Act of 1947 (the so-called Taft-Hartley Act), unions achieved definite legal status as parties to contracts; the rights of employers in industrial relations were redefined more favorably, and the rights of labor were partly restricted; and the scope of governmental intervention in strike situations was enlarged.

The Labor Contract.—In its basic legal aspect, the capital-labor relationship is a contract in which the contracting parties are the employer and employee. As shown above, the emergence of the labor contract marks the outcome of efforts to preserve individual bargaining as the exclusive or paramount mode of defining the employment relationship, and of counterefforts to introduce controls over the bargaining process intended to offset the disadvantage of labor.

The upshot has been the development of labor and social legislation and collective bargaining. Statutes and administrative enactments and judicial decisions made thereunder greatly restrict the freedom of the parties in bargaining by establishing minimum limits for the terms which enter into labor contracts, determining conditions under which labor contracts are negotiated, providing for the disposition of labor-management disputes, and restricting the right, primarily of employers, but also to some extent of employees, to enter into and to terminate labor contracts at will.

Collective-bargaining agreements are similar in effect. Formerly, they were not regarded as contracts and were not enforceable at law. Later,

the common-law development of union rights crystallized a judicial tendency to recognize collective agreements as contracts. By provisions of the Labor Management Relations Act of 1947 they were made binding contracts, enforceable through suits by and against unions.

In form, the labor contract continues to be an agreement between employer and individual employee. In substance, it is increasingly, as the scope of collective agreements and social legislation is enlarged, a means of effecting a relationship, the characteristics of which are predetermined by agreement and can be altered subsequently by further agreement.

THOMAS STAMM.

INDUSTRIAL ORGANIZATION AND ADMINISTRATION. In the early years of American business, administrative control was a matter of private or family-owned organizations of the simplest sort. The first large undertakings requiring corporate form and a scheme of formal financing were the toll roads, canal companies, and the railroads. The chief factor which caused an increase in the size of businesses during the half-century 1840-1890 was the invention of machinery. The large-scale operation which machinery and the use of mechan-

ical sources of power suggest has been realized because of the enormous domestic market, the ample capital available, the freedom of the country from tradition and the existence of a spirit of daring. By the decade 1895-1905, these experiments had sufficiently developed the technical aspects of manufacturing that engineers could boldly plan groups of specialized plants under united control. In the meantime, the accountants had learned how to keep untangled the most heterogeneous affairs; and the distributive or marketing machinery was devised for handling the entire domestic market in a single campaign. Since the possible economies from the elimination of competition were very large, there occurred the so-called "trust movement," which resulted in the consolidation of many hundreds of individual plants into a small number of great consolidated corporations. In the process of putting these enterprises together, and of operating them, the art of corporation financing, and its underlying technique of accounting, have achieved a forced growth.

Overlapping this period in part, but operating most intensively from 1910 to 1914, there occurred the movement known as "scientific management." Broadly speaking the purport of this movement is that a group of engineers applied the precise and systematic methods of investigation and calculation recognized in the engineering sciences to the study of shop processes, and that by so doing they uncovered astonishing inefficiencies and were able to recommend a system of functionalization of shop executives and a policy of standardization upon the best methods which systematic study should discover. Scientific management is an effort to apply the scientific method to a certain portion of the shop practice. It met with determined opposition because it did not adequately apply the knowledge and spirit of the times in its handling of the wage earner. A further account of this movement may be found under the heading **SCIENTIFIC MANAGEMENT**. At the present time the interest of business executives in the evolution of new methods centers in "human engineering." There has been an accumulation of knowledge concerning hygiene and public medicine, the causes of fatigue and accidents, and the wastes of the hiring-and-firing methods in vogue, which demands application. It is realized that men should be carefully chosen for their work and given special training for it. Organized labor has enforced the idea upon the public mind that the laborer should have a voice in determining the conditions in which he works. And finally there are new ideals of the "square deal" and of service which are making their way among the more advanced employers.

Departments of Business Administration.

—The ordinary functions of business administration fall into four classes: (1) financing—in charge of the chief officers, working in close relations to the board of directors; (2) manufacturing—in charge of a general manager, or superintendent, directing a corps of foremen in the shops; (3) selling—under the direction of a sales manager, with district agents and salesmen; (4) personnel relations—in charge of an employment manager or superintendent of personnel.

Financial Organization and Management.

—If the inauguration of a business takes the usual course of large modern enterprises, there will first appear upon the scene a promoter

who discovers undeveloped properties or poorly-managed concerns, forms a plan for their development, secures options upon them and puts his project before capitalists. Capital may be represented by a syndicate manager, who acts for a group of banks and large private investors in investigating the projects presented. If a project be found meritorious, its financing will be taken over on conditions which ensure adequate control of the subsequent operations of development. A corporation will then be formed which, under its charter powers, elects officers, enters into contracts, issues securities, receives funds, secures plant and equipment and otherwise prepares to do business.

The liabilities of a business corporation may be briefly listed as bonds, short-term notes, preferred stock, common stock, commercial paper and open accounts. The bonds of manufacturing enterprises (unless the business of certain public utilities be included therewith) should represent but a small fraction of the total capital, for the reason that the earnings of such businesses have, in the past, been subject to violent fluctuations. Preferred stocks are a business man's risk. They may be described as intermediate in security between bonds and common stocks. They will, in many cases, represent the cash and property contributed to the business by the group of interests connected with its organization and development. Common stocks receive dividends only after interest on the bonds and dividends on the preferred stock have been paid. There is no margin of safety to protect them. Their hazard is not so much the correctness of the process of valuing assets as it is the skill of the management in earning income. They are an appropriate investment only for men of means who are intimately associated with industrial management.

The financial authorities of a business are responsible to allot the funds raised from the issue of securities as advantageously as possible to the various requirements. A portion will go into buildings and equipment and other relatively permanent forms. This may be designated as fixed capital. Another portion must be reserved for raw materials, finished stock, pay roll and credit advances to customers. This is circulating capital. Fixed capital loses value slowly as a result of wear and tear. Circulating capital changes its form of investment rapidly. A balance in the bank last week may have been paid out as wages and be now represented by goods in the warehouse. Next week, if the goods are sold, it may take the form of a credit advance to a customer.

As fixed capital is relatively enduring, a large amount of funds should not be put into such a form until it is certain that the enterprise is to be of a permanent nature. Fixed capital may be of various degrees of specialization. The more specialized the form the more difficult it is to sell, and the more its selling price depends upon the hazard of a single set of market conditions. The degree to which it is proper to specialize capital is a function of the conference felt in the soundness of the project. The utilization of fixed capital is a process requiring the continuous supplying of circulating capital. Materials and labor must be provided to support the process of produc-

tion. A plant is valueless when not in motion. To keep it under headway money must be constantly poured into it in amounts which in the average case may equal the total capital of the business annually. It is a somewhat common error of business finance to place an unduly large proportion of the assets in fixed form. The homely caution of Poor Richard may well be remembered, "It is easier to build two chimneys than maintain one in fuel." The financial organization of a private business connects with the general financial machinery of the country through the company's published reports, through the certified public accountant who vouches for the report he signs and through the general banking system. It is further connected by the investment bankers who purchase the securities after investigation and sell them to the investing public, by the stock exchanges which exert some slight control over the probity of the methods of the corporations whose securities they admit to listing privileges, by State commissions which are rapidly taking over the functions of authorizing security issue and by the general machinery of law. See INDUSTRIAL DISTRIBUTION.

Administration of Manufacturing Processes.—The highest authority in a business, on matters pertaining to productive processes, may be known as the general superintendent or works manager. In the initial stages of the business this officer will have the leading influence in determining the location of plants, the layout and character of buildings and the selection of machinery. When preliminary plans result in the construction of a mechanical automaton, and it becomes necessary to add men and materials and to indicate methods of production, in order that the enterprise can become a going concern, the general superintendent will take on a much expanded range of responsibilities. He will be expected to keep the physical equipment and productive processes up to standard and to employ an adequate force of foremen, laborers and skilled men of the various crafts. He will control the progress of work in relation to the demands of the sales department by a schedule and a system of orders, which control all productive labor and the use of material. The design of articles and the accuracy of manufacture is effected through a designing department and a system of inspectors. As a means of improvement he will use time studies and motion studies. The information thus accumulated he will embody in standards, which will be promulgated as the prescribed methods. The ideal is standardization, which is such an effective control of performance that every case conforms to the rule laid down. These prescribed methods will be communicated by general or standing orders and by shop orders. In a business of any size, orders should be written. The standing orders, when gathered together, will compose a "book of rules." The shop orders will be supplemented by instruction cards, to convey precise information as to the materials to be used, the machine or tool to employ, the process to select, the time the task should take, the machine adjustments, etc., etc. A particular instruction card will be prepared in advance for each task, and will be issued from the planning room, for the workman's convenience, each time the job is given out.

The planning room is the chief service aid of the superintendent and the foreman on technical matters. It may, in a typical instance, contain a routing or order-of-work clerk in charge of the planning board, an instruction card clerk, a clerk in charge of time slips and cost records; and it will probably serve also as headquarters for the engineer who calculates the proper speed of machinery, and the time study man who studies manual operations.

From the foregoing statement of duties it can be seen that the general superintendent has a very wide range of responsibilities. To be able to function efficiently, in the face of the enormous evolution of science and technique which has taken place in recent years, he should confine himself to general supervision, entrusting details to a staff of specialists. There has grown up in the best-managed businesses a number of service departments or staff aids for the express purpose of relieving the general superintendent. Such are the tool room, the stores department, the engineering department, the designing and drafting room, the inspection department and the planning room. Usually also the cost department and the employment department will be answerable to him. To a considerable degree the difference in efficiency of manufacturing enterprises depends upon the ability of the superintendent to comprehend the functions of service departments, and his success in organizing about him a staff of specialists who relieve him and his foremen. An executive blockade exists in many businesses because the general superintendent and foremen are overloaded. The remedy is to apply the principal of specialization and division of labor in administration, as it is applied among the craftsmen and common laborers in the shops.

Administration of Personnel Relations.—

Within the last 15 years, the attention of business executives has been increasingly drawn to the problem of employment management, or as it is sometimes called, "human engineering." For years the demand of labor organizations, and the waste and violence of strikes, have made the "labor problem" synonymous with a class contest over the sharing of the product. Recently, the relation between employer and employee has begun to take on a different character. It has been found that a great many things can be done which will benefit both. A field of harmonious policies has opened itself. The labor problem begins to appear to be a matter of the careful selection of men for their work, the provision of comfortable working conditions, the prevention of accidents, the safe-guarding of health, the careful setting of wages on the basis of an honest study of all the facts, including the cost of living, and a variety of activities which develop interest in work, loyalty to a common cause, and the mutual welfare. Experience has proved that these problems can best be handled by having a separate department of the business, which can devote itself to them; and by putting in charge of this department a first-class executive. The movement to install such officers is a resultant of progress in accounting, staff organization, functional foremanizing, vocational guidance, industrial training, the new

wage systems, safety first, hygiene and medical aid, and the use of the committee system of shop management. The functions of the employment department are, for the most part, not new in industry. They are now being gathered together under one authority so that they may be handled in a more expert manner, that they may be harmonized into a consistent policy, and that they may be made the definite responsibility of competent officers. Among the causes which are responsible for the attention now being given to personnel supervision is the extension of cost accounting to the factors which influence labor efficiency. The cost of labor turnover is being calculated. The cost of accidents, of sickness, of absenteeism, of improperly placed men and of strikes is being studied. The employment manager is, in one sense, a labor-cost accountant. The organization of an employment department does not involve an increase in the cost of doing business. On the contrary, it means an economy, by reason of a reduction in the number of persons to be trained, a saving of foremen's energy, a reduction in accidents and a gradual increase in the average skill and experience of employees. Proper employment conditions attract superior workmen, and generate a co-operative spirit; this affects favorably the rate of production, the waste of stock and the quality of output. See LABOR TURN-OVER.

The employment manager is necessary to apply the art of mental testing and vocational guidance in ascertaining the fitness of prospective employees. He best can direct industrial training to provide the talent which the employment records show to be most needed. He knows the process of establishing fair base rates of wages, of working out wage scales, of checking minimum rates against the local cost of living, and of planning simple and specific production bonuses. The employment manager has come in with safety first, because it has been found that three-fourths of the accidents are due to the carelessness or ignorance of the working force. His department works along the lines of hygiene, sanitation, medical aid, canteens and health education, to cut down accidents, reduce fatigue and cure antagonism of mind. Employment supervision represents a movement in the direction of the democratic shop, in which a voice is given to labor in determining the working conditions. It is a means of applying that conception of truth and service which has revolutionized selling and advertising. As the customer is "sold" goods—that is to say is thoroughly convinced and satisfied—so a workman is "sold" his job. The latter has to be satisfied as to the task, the working conditions, the wages and the general policies, before he becomes a genuine employee.

The employment manager is coming in as a new staff man to relieve general executives. Staff or service departments are already familiar in the form of accounting departments, statistical departments and the like. This principle of staff service is now being carried over into the field of human engineering. General executives are demanding well-chosen men, men who are free from accidents and in sound health, men satisfied with their pay, and men

so treated that they form a permanent and contented force, ready to cooperate loyally in the general plans of the enterprise. Of all the standardized agencies a service department can furnish to a general executive, the greatest is a first-class man. In a somewhat analogous way the employment manager represents a step in specializing the work of the foremen. His coming makes the foreman less of a jack of all trades, just as the coming of the tool room, the stock room and the designing department did. When the foreman becomes accustomed to the new system he finds it a great relief. He gets a more even and dependable run of men than he could provide for himself, and he is free to become an expert in shop processes.

EDWARD D. JONES.

INDUSTRIAL RELATIONS. See **INDUSTRIAL OR LABOR RELATIONS IN THE UNITED STATES.**

INDUSTRIAL RELATIONS COMMISSION. A commission created by act of Congress Aug. 23, 1912, for the purpose of inquiring into the general condition of labor in the principal industries of the United States, including agriculture, and especially in those industries which are carried on in corporate forms; into existing relations between employers and employees; into the effect of industrial conditions on public welfare and into the rights and powers of the community to deal therewith; into conditions of sanitation and safety of employees; into the growth of associations of employers and of wage earners; into the extent and result of methods of collective bargaining; into any methods which have been tried in any state or in foreign countries for maintaining mutually satisfactory relations between employees and employers; into the methods of mediation and conciliation; into the scope, methods and resources of existing bureaus of labor, and into possible ways of increasing their usefulness; into the question of smuggling or other illegal entry of Asiatics into the United States or its insular possessions, and of the methods by which such Asiatics are gaining admission, and to report to Congress recommendations for remedying existing difficulties. The commission consisted of nine members, including three employers of labor, three representatives of labor organizations and three representatives of the public at large. It separated its work into two large divisions, public hearings and research and investigations, and published valuable reports. It expired in August 1915.

INDUSTRIAL REVOLUTION, The. Towards the end of the 18th and the beginning of the 19th century there occurred in England a series of changes in methods of industrial technique and radical alterations in the social and economic organizations. This transformation was characterized by Jérôme Adolphe Blanqui in 1837 as an "industrial revolution," a term which was popularized by Arnold Toynbee in 1880 and has since been used to denote these events. The older idea, given currency by this name, was that a sudden and revolutionary change was wrought in English industry by a dramatic series of new inventions; but more current research has shown that the old system was modified only gradually by a succession of changes which took a long time to work out. Economic history never makes sudden and unanticipated jumps.

Two interesting questions suggest themselves at this point: (1) Why did the Industrial Revolution take place at the end of the 18th century? (2) Why in England?

(1) "Necessity is the mother of invention," says an old proverb, and this suggests the answer to the first question. Productivity in almost every line was limited by ineffective methods and inefficient tools. In agriculture the appliances in use at the time of the Pharaohs were still being employed: grain was sown broadcast, fields were tilled with crude wooden plows, and the harvest was cut with a sickle and threshed with a flail. In the textile industry, the oldest and most important of all, the methods of Penelope in the time of Homer were still used, with the exception that the spinning wheel had been substituted for the distaff and spindle, though this still produced only one thread at a time. In the mineral industry there was promise for the future in some significant changes which were beginning to be made in processes that dated from the time of Tubal-Cain of the Old Testament era. But in transportation great improvements had already been made that were to open up new opportunities. Discussion of this topic must, however, be deferred until the second question is answered.

(2) Why in England? At the end of the 18th century pure research in the physical and chemical sciences had progressed far on the Continent, especially in France and Holland, but the English excelled in the application of scientific knowledge to practical affairs, particularly in industry. There was a general interest in mechanical improvements. Political, social, and legal conditions in England were also favorable to industrial development. Political liberty, freedom from illegal persecution, sanctity of property rights and of contracts, a patent law, religious freedom, and the opportunity of climbing the economic and social ladder created a climate favorable to enterprise. The factors just mentioned were on the side of supply and explain why it was possible for England to take the lead. But the real driving force must be sought on the side of demand, and this brings us back again to the subject of transportation.

The British at this time had the greatest merchant marine in the world and controlled much of the commerce. They possessed, either at home or in the colonies, practically all the raw materials necessary for the development of extensive industries. At home there were wool, coal, and iron, and in the colonies were iron, cotton, dyewoods, lumber, and naval stores. A large actual, and a still larger potential, market existed for the wares that might be produced from these raw materials. This condition was appreciated by shippers and traders and most of all by merchants, who saw that the exploitation of the possible market required improvements in processes of manufacture. All of these materials lent themselves to mass production, lower costs, and larger sales, and strong pressures therefore existed to meet this demand for cheaper methods of production.

Textile Industry.—The first large response occurred in the textile industries. It is not necessary to describe here the remarkable series of inventions in spinning and weaving machines which revolutionized processes, enormously increased output, and also reduced cost per unit. At first these inventions were applied to the woolen industry, but after the American, Eli Whitney, invented the cotton gin (1793), which increased

and cheapened raw cotton, they were used to process this fiber. The manufacture of cotton goods now became the leading industry.

But in order that the new machines might be utilized to the utmost it was necessary that they be driven by some nonhuman power. It cannot be emphasized too strongly that the vital feature of the Industrial Revolution, and the one which constituted a complete break with the past, lay in the substitution of power for human muscle. So long as man was confined to the use of hand tools his powers of production were strongly limited by the number of human hands available for this purpose. But as soon as power-driven machinery was introduced there was no limit placed upon his ability to produce.

This brings us to another step in this complex development—the invention of the steam engine. Thomas Newcomen had invented such a machine in 1705 to pump water out of flooded coal mines. It was while repairing one of these crude machines in 1764 that James Watt invented improvements that foreshadowed the modern steam engine. At first used for pumping and hoisting coal to the surface, the improved machine was soon adapted to the driving of the new textile machinery and to other uses. It must not be supposed, however, that the modern steam engine sprang at once into being, for a whole series of other inventions were necessary to improve it. Cylinders bored by hand were distressingly irregular until John Wilkinson invented his cannon-boring machine in 1774 and Henry Maudslay his slide rest in 1794. These produced cylinders so accurately bored that the pistons would fit in them without waste of steam. The modern machine was now realized.

Iron and Steel Industries.—The second industry which was transformed by inventive genius was the production of iron and steel, which was now badly needed for the construction of the new machines. The smelting industry was one of the oldest in England, but it suffered from the exhaustion of the forests which had provided fuel (charcoal). Experiments in the use of coal as fuel were carried on during most of the 18th century and by its end the smelting of iron by coal or coke instead of by charcoal had been almost universally adopted. But this was only the first step in a complex metallurgical process. The pig iron must now be converted into steel. Further inventions made this possible, with improvements being made in the blast, the substitution of rollers for hammers in shaping the malleable iron or steel, and in appliances for handling heavy castings. It was now possible to make strong and powerful machines, for which there was an ever-increasing demand.

Economic and Social Aspects.—The final stage in the Industrial Revolution was a momentous one. Until the new inventions revolutionized methods of production, industry had been carried on under the domestic system, in which artisans conducted their crafts on a small scale in their homes. But there gradually emerged enterprisers who gathered the domestic workers together in workshops, where they provided the tools formerly owned by the workers. When the new machines appeared, which were too expensive for the artisans to buy, it was but a short step for the enterprisers who possessed sufficient capital to organize production under the factory system. Thus was born a new system of capitalistic organization which has since characterized modern industry.

The factory system brought far-reaching

changes. In the first place, since they controlled the new machines, the capitalists were able to dominate all the processes of production, the place of working, the scale of wages, and the kind of workers. Improvements in agriculture, due in part to improved tools and in part to enclosure of the land, produced a larger supply of food and released many agricultural laborers from the land. This supply, together with child labor which could be used to tend machines, depressed wages and raised profits. The capitalists were now in the saddle. A sharp schism developed between capitalistic enterprisers and wageworkers, with the latter group becoming increasingly dependent upon the former for employment and the seeds being sown for a bitter struggle between capital and labor which continued for another century. (See *FACTORY SYSTEM*.)

But the results of the factory system were not all bad. Although the wealth was very unequally distributed and wealth and poverty moved hand in hand, a great increase in productivity nevertheless enormously augmented the wealth and power of the nation. At the same time industry became increasingly integrated and large-scale. It was also more and more complex and interdependent. The essential feature, however, is the ascendancy of the capitalistic organization of industry.

It is not surprising to find that economic theory accommodated itself to the new conditions. The classical economists were the apostles of *laissez faire*, of free trade, and of noninterference with trade and industry. Government control was reduced to a minimum. Even legislation for the protection of child labor and of exploited workers could not make headway against the massive pressure groups that thwarted every effort at reform. The Act of 1819 is often cited as the first factory labor act, but it covered only cotton mills. The Act of 1833 was the first really effective act, covering all textile mills, setting the minimum age for child workers at nine years, and providing for inspection and school attendance.

One conclusion that may be drawn from the events of the Industrial Revolution is that its achievements were the result of the cumulative efforts of a great many individuals, with each building upon the success of his predecessor. Today improvements in technical processes are usually the result of teamwork, probably financed and directed by some great corporation. The success of the early pioneers, working alone, may well command our admiration.

A final word should be said. The Industrial Revolution, which transformed the social and economic organization of England, is still going on. It has spread geographically to the ends of the earth. The Age of Steam has given way to the Age of Electricity, and there is a future promise of an Age of Atomic Power for peaceful purposes.

INDUSTRIAL SCHOOLS. See **TRADE SCHOOLS**.

INDUSTRIAL TERMS. Following is a glossary of common terms used in industry. Terms not appearing here may be found in separate articles under their own headings or in some of the following: **AERONAUTICS**—11. *Aeronautics Glossary*; **ATOMIC AND NUCLEAR TERMS**; **AUTOMOBILE GLOSSARY**; **BANKS AND FINANCE**—29. *Glossary of Terms*; **CHEMISTRY**—4. *Chemical Glossary*; **COMMERCIAL TERMS**; **ELECTRICAL TERMS**; **ENGINEERING TERMS**; **FOUNDRY AND FORGE SHOP TERMS**; **GRAPHIC ARTS**—*Glossary of Graphic Arts Terms*; **HOSIERY INDUSTRY AND HOSE—Hosiery Terms**; **LABOR TERMS**; **LEATHER AND SHOE TRADE TECHNICAL TERMS**; **SHIPPING AND SHIPBUILDING TERMS**; **STEEL**—6. *Glossary of Steelmaking Terms*; **VALVE TERMS**; **WORKSHOP TERMS**.

In this glossary, cross references in *italics* are to other headings in the glossary; other cross references are to separate articles.

Acid-test Ratio.—A financial analysis ratio indicating a firm's relative ability to meet its current obligations. It is determined by dividing liquid assets (cash or its equivalent) by liabilities that must be met with cash in the near future.

Adder.—In color television, a device that integrates three individual color signals into a brightness signal for transmission.

Adit.—See *Drift*.

Advanced Gallery.—The small opening cut in front of the main shaft when excavating a tunnel; the area in which the workers are actually cutting on the tunnel face.

Afterbay.—The water outlet of a water-operated turbine power plant.

Afterdamp.—A gas, usually consisting chiefly of carbon dioxide and nitrogen, which remains in a mine after a mine fire or explosion.

Aging.—(1) Subjecting electron tubes to various current loads in order to stabilize their operating characteristics. (2) Storing various food products under controlled conditions to improve their flavor. (3) In accounting terminology, determining how long various debtor or creditor accounts have been left standing on the books.

All-sliming.—Crushing ore in a mill into fine particles. **Allen-O'Hare Furnace.**—A horizontal double hearth furnace for calcinating sulphide ores.

Almond Furnace.—A furnace in which litharge (lead monoxide) slags left from refining silver are reduced to lead.

Alpha Brass.—A copper-zinc alloy with a copper content of above 64 per cent.

Annular Bore.—Tool with a hollow cylindrical bit used to cut cores for earth samples (see *CORE*).

Anode Copper.—Crude copper plates cast at a converter and used as anodes (see *ANODE*) in further electrolytic refining.

Anodize.—To use a metal as an anode (q.v.) in a chemical bath in order to give it a desired coating.

Anticline.—See *ANTICLINE*; *FOLDS*.

Arch.—In mining, a portion of a lode left standing because it is too poor to work or is needed as a support.

Archimedean Screw.—See *ARCHIMEDES' SCREW*.

Arents' Tap.—Device for drawing off molten lead from the interior of a shaft furnace without disturbing the furnace.

Argil.—Potter's clay.

Babbitt Metal.—See *BABBITT METAL*; *ANTIFRICTION METALS*.

Back.—(1) In metal mining, the portion of the lode that lies between a level and the one next above it, but has to be worked from below. (2) In coal mining, the inner end of a heading where work is being conducted. (3) In the leather trade, the thickest and best hides.

Back Slope.—Supporting timbers across the top of a

mine shaft, usually fitted into notches in rock.

Back Tender.—A man who ladles paint pastes into color boxes for textile printing.

Bag Molding.—The process of shaping precut sections of glass mat over cloth on a mold and applying molding resin, heat, and pressure to bond the materials. The technique is usually employed for molding large plastic shapes.

Bagasse.—See *BAGASSE*.

Baking Out.—The process of drying graphite and phosphor coatings on electron tubes by subjecting them to heat which simultaneously anneals the bulbs.

Band.—A strip of minerals interstratified with coal.

Barff's Process.—A process for protecting iron from rusting by oxidizing it with superheated steam.

Barrel Work.—Pieces of native copper too small to be handled as mass copper, but large enough to be shipped in barrels.

Base Box.—A standard unit of measure in the tin can industry, equal to 31,360 square inches.

Basing Point.—Some point, usually an industrial or railroad center, from which freight charges to customers are figured. It is frequently not the place of production, and the item shipped does not necessarily pass through that point.

Basque.—A lining for furnaces or crucibles.

Bastard Cut.—Very coarse spacing of teeth on a file.

Bat.—In ceramics, a flattened circular piece of clay ready for mold-spinning of a plate or saucer.

Bating.—Soaking operation to loosen scud and plumping from leather, rendering it soft and fit for tanning.

Batting Block.—In ceramics, the plaster slab on which clay is beaten before forming.

Beading.—Process by which a thin lip of metal is curled over on itself to increase its strength and eliminate its sharp edge.

Beater.—In papermaking, a large kettle in which water and caustic soda are added to wood pulp, also used for mixing in special finishing materials for specific papers.

Beaumontage.—The filling material used to stop small holes in wood or metalwork. For wood it is made of varnish thickened with chalk and resin; for iron, of iron filings mixed with sal ammoniac.

Beehive Oven.—See *COKE*.

Beetle.—A heavy wooden mallet used to drive wedges.

Beneficiation.—The process of increasing the concentration of metal in low-grade ores before smelting. See *IRON*—4. *Pig Iron*; *METALLURGY*—4. *Extractive Metallurgy*.

Beta-ray Gage.—A device for measuring the thickness of a material by measuring the amount and intensity of beta rays passed through it.

Binder.—A material used to hold particles of sand together in the desired shape during sand molding.

Bittern.—The liquor remaining in salt processing after the salt (sodium chloride) has crystallized out. See also *SALT*.

Blackjack.—Sphalerite (zinc blende or sulphide of zinc).

Blanché Copper.—A copper-arsenic alloy.

Blast Gate.—A device for controlling the pressure on gas turbine blades by releasing gas from the nozzle box to the free atmosphere.

Bleeding.—(1) In textile printing, the spreading of dye on cloth. (2) In publishing, printing beyond the margin or to the edge of a page. See also *GRAPHIC ARTS—Glossary of Graphic Arts Terms* (Bleed).

Blind Screening.—A pharmaceutical research technique of exposing disease-causing agents almost randomly to various compounds to see whether the compound eliminates the agent.

Blooming.—Rolling an ingot into a rough shape with a square or rectangular cross section having an area of 36 square inches or more. See also *ROLLING MILLS*.

Blow.—(1) One complete cycle of removing impurities from steel by the Bessemer process. (2) Letting air out of a working chamber so that a caisson can drop into place.

Blue-short Iron.—Wrought iron made brittle by being worked at blue heat.

Blunger.—A mixer for clays in earthenware manufacture.

Board Hammer.—A small gravity-operated drop forge lifted by rollers operating against boards.

Body.—The mixture of clay and powdered rock from which brick and tile are made.

Bonanza.—A body or pocket of rich ore.

Boom.—A long beam or spar projecting from a derrick or similar device used for lifting or moving.

Boring.—See *BORING* and *BORING MACHINES*.

Borsella.—A device used to stretch or contract glass during its manufacture.

Bottom Hole Contribution.—Amount paid to an oil driller when he reaches a certain depth regardless of whether the well produces oil.

Bow Tie.—A type of antenna, named from its shape, used for transmitting or receiving television signals.

Brood.—A mining term applied to all heterogeneous mixtures found with copper or tin ore.

- Bubble Tower.**—A tower used for fractional distillation of oil or other complex chemical substances.
- Bulling Bar.**—In mining, the bar used to ram clay fillings into open cracks before blasting.
- Bumping.**—(1) Flattening the side seam of a cylindrical can after edges are hooked. (2) The practice by which a senior laborer replaces a junior laborer at another job during a cutback in the production force.
- Bundle.**—(1) In papermaking, 2 reams of printing or brown paper. (2) In spinning, 20 hands, or 6,000 yards of linen yarn.
- Burden.**—A term commonly applied to the overhead costs of an operation. Burden rate refers to the ratio used in allocating burden costs to units of production, such as dollars per direct labor dollar, or dollars per square foot of space used.
- Burner.**—A kiln fireman.
- Butt Weld.**—Joining two pieces of metal by placing the surfaces to be welded close to each other, then building up the weld between them.
- Cable-tool Drilling.**—A method of drilling wells by pounding a hole into the ground with a heavy bit attached to a cable.
- Cade.**—A term of measurement in the fishing trade, denoting either 500 herrings, or 1,000 sprats.
- Cambering.**—(1) Placing curvature in a rail or beam to compensate for unequal cooling of head and base so that rail will be straight when cool or when under dead-load conditions. (2) Setting wheels of an automobile closer together at bottom than top.
- Camelback.**—An uncured compound of rubber, mostly reclaimed, used for retreading or recapping tires.
- Candle.**—To determine the internal characteristics of translucent materials by passing a light through them.
- Carboy.**—A large glass bottle used for transporting acids.
- Carding.**—In textiles, preparing fibers for spinning. See also **CARDING; TEXTILE MACHINERY.**
- Carrier.**—(1) The basic signal frequency upon which information is mounted in point-to-point or broadcast electrical transmission. (2) A chemical agent or catalyst which enables the transfer of some element or group from one compound to another. (3) One who transports on behalf of another.
- Cat Cracking.**—Catalytic cracking (see **Cracking**).
- Catalyst.**—A chemical which assists or controls a chemical reaction without being one of the agents in the reaction.
- Chassis.**—The metal framework to which mechanical or electronic components are attached.
- Checker Chamber.**—The heat-exchanging brick chamber through which hot gases pass in open-hearth or blast furnaces. The name is derived from the checkerboard pattern of holes through which air passes.
- Cheek.**—The center part of a three-part sand mold.
- Choker.**—A short length of wire rope used in logging.
- Christmas Tree.**—The system of valves and controls used at the ground surface to control the flow of oil from a producing well.
- Chuck Machine.**—A semiautomatic lathe (usually with multiple spindles) which must be fed each piece individually; that is, it does not have a provision for automatic throughput of bar stock.
- Churn Drill.**—A mobile drill for digging wells. Cutting action is created by repeated dropping of a cable-lifted ream. The ram bit pulverizes rock and soil as it strikes.
- Cloud Point.**—The temperature at which paraffin wax and other solid substances begin to crystallize out of petroleum vapor as it is cooled.
- Cobble.**—A piece of steel so twisted or bent that it cannot be rolled.
- Cockle.**—(1) In porcelain making, a large stove used to dry the biscuit ware after glazing, preparatory to burning. (2) The kiln used for drying hops.
- Coil.**—In electricity, a loop or loops of insulated wire through which current is passed. See also **INDUCTION COIL.**
- Coke Tower.**—A coke-filled condensing tower used in the manufacture of hydrochloric acid. Water is sprayed down from the top to mix with rising hydrochloric acid gas.
- Cold Mix.**—A mixture of asphalt or tar that can be laid without extensive heating.
- Cold-short Iron.**—Iron that is weak and brittle when cold because of the presence of phosphorus.
- Collier.**—(1) A vessel for carrying coal or other bulk commodities. (2) A worker in a coal field.
- Collodion.**—An insulating material used to bind electrical coil windings.
- Combing.**—See **TEXTILE MACHINERY.**
- Common Return.**—A single wire or pipe which serves as a return path for electricity or fluid from several output systems.
- Compression Molding.**—Shaping plastic materials in dies by simultaneous application of heat and pressure.
- Condensate Crude.**—A crude oil which gives a high yield of low-boiling-point condensates.
- Cone.**—In textiles, a cylindrical spool of yarn or thread usually wound from a skein.
- Cope.**—The upper half of a mold used in sand casting.
- Core.**—(1) The baked sand mold used to form an internal shape in a sand casting. (2) The cylindrical sample of subsurface geological formations obtained by drilling with a hollow drill.
- Cottle.**—A flexible form used to cast clay to the approximate form desired.
- Count.**—In textiles, (1) the relative diameter of threads as measured by the weight of a stated length. Single-thread counts in cotton are the number of hanks of 840 yards in 1 pound; that is, a 20-cotton thread is 20 hanks to the pound. In worsted, the basis is 560 yards to the pound. In wool, it is the number of 1-yard skeins in 1 dram. (2) The number of picks or threads to the inch in a woven fabric, as 60-count.
- Counterbore.**—To bore a shallow cylindrical recess of larger diameter at the surface end of a hole. The counterbore usually serves as a seat for a bolt head or washer.
- Countersink.**—To cut away material at the surface end of a hole so that the head of a flathead screw would be flush with the surface.
- Cracker Mill.**—A mill that breaks up rag stock in rubber-shoe manufacture.
- Cracking.**—The process of breaking a complex organic molecule into more elementary parts by means of heat and pressure (thermal cracking) or with the assistance of a catalyst (catalytic cracking). The elementary parts are then used to build new and different molecules. See **CRACKING PETROLEUM.**
- Cradling.**—In construction, placing cables of a suspension bridge closer at the center of the bridge than at the tower ends.
- Crazing.**—(1) Fine cracks that extend over the surface of a molded plastic or penetrate through a thin section of it. (2) In ceramics, when the glaze separates from the body and forms blisters.
- Creel.**—A device onto which yarn on bobbins is placed before weaving.
- Cropping.**—Removing metal from the bottoms and tops of ingots after semifinishing.
- Crosshauling.**—The shipment of goods by producers into each other's territories before the demand in their own territories is filled, the extra shipping caused by greater area competition under the basing-point system.
- Cull.**—In plastic molding, the excess material in the molding machine's transfer chamber after the molding cycle is complete.
- Cullet.**—In glass manufacture, the clean waste and broken glass from previous meltings and castings which is added to a raw batch to initiate the fusion.
- Current Ratio.**—A ratio indicating a firm's relative ability to meet its current obligations. It is determined by dividing current assets by current liabilities.
- Cutbacks.**—Petroleum residues fluxed with distillates.
- Cuts.**—Crude distillates drawn off from an oil-fractionating tower.
- Dabbing.**—In stoneworking, the process by which the surface of the shaped stone is covered with small pecked indentations.
- Dag.**—A graphite coating placed on the inside of a cathode-ray-tube bulb to form the high-voltage anode.
- Damask.**—Surface imperfections on polished steel caused by corrosion.
- Dandy Roll.**—In papermaking, the wire-gauze cylinder beneath which the web of water pulp is passed to drain it partially of water and impress the watermark.
- Dap.**—To notch a timber.
- Dead Load.**—A steady nonvariable weight acting on a structure.
- Decoder.**—In a color-television electronics system, a device to break up the color information signal into red, blue, and green signals.
- Defecation.**—The process of removing impurities from fluids or materials.
- Dehydrogenation.**—The process of cracking more complex molecules and forming new molecules by removing hydrogen.
- Demurrage.**—A charge for holding a railroad car beyond specified time limits.
- Den.**—A storage bin used for bulk items.
- Depletion.**—(1) The actual exhaustion of mineral resources or (2) an accounting charge that amortizes the cost of a deposit against revenues derived from selling the minerals.
- Depreciation.**—See **ACCOUNTING.**
- Desizing.**—Removing the sizing from cloth before finishing operations. This usually involves dipping the cloth in solvent and washing it in clear water.
- Detail.**—A small part of a construction or the drawing of a particular part.
- Development.**—A stage in scientific research in which known principles are applied to the solution of a par-

- tical problem. Development includes the construction or synthesis of experimental (prototype) devices or materials.
- Digester.**—In paper processing, a large refining unit where beaten pulp is cooked.
- Dip Needle.**—In prospecting, a magnetic needle that swings in the vertical plane and dips toward certain mineral deposits.
- Dip Soldering.**—Soldering electrical connections by lowering the chassis, with components mechanically attached, into a shallow tray of hot solder. The solder flows up the crimped leads of the components by capillary action.
- Diplexer.**—A device for integrating two signals of different frequencies to be transmitted from the same antenna.
- Dissociation.**—See DISSOCIATION.
- Doctor.**—The sharp metal scraper used to remove paper from the Yankee dryer in the first stages of paper processing.
- Dolly.**—(1) A soft polishing mop rotated at high speed for putting the final surface on metalwork to be plated. (2) In mining, a heavy tool, sometimes of wood, for crushing soft materials. (3) A rack or frame mounted on small wheels and used to move heavy loads.
- Dose.**—A special charge of materials inserted into a blast furnace to correct its faulty operation.
- Drafting.**—Straightening the fibers in a textile sliver and elongating it for spinning.
- Draw Spike.**—A pointed steel rod with a loop on one end, used to remove the wood pattern from a sand mold.
- Draw Works.**—The portion of oil-drilling apparatus used to raise and lower drill pipe and sometimes also to operate the rotary table that drives the drill.
- Drawing-in.**—In textiles, threading warp ends through drop wires, heddle eyes of the harness, and dents in the reed prior to weaving fabric on a loom.
- Drift.**—A nearly horizontal passageway into a mine.
- Drifting.**—Mining along a shaft following an ore vein.
- Drill String.**—In oil drilling, the hollow drill shaft extending from the surface to the rotary bit.
- Dross.**—Metal oxides in metal or alloys, particularly in the manufacture of copper and brass products.
- Dry Hole.**—An oil well dug to a specified depth without striking oil.
- Dummy.**—In plumbing, a wooden rod having a lump of lead at the end, used for ramming out dents in lead pipe.
- Duplexing.**—Using molten steel to charge an open-hearth furnace.
- Electrical Logging.**—Determining the oil or salt-water content of formations drilled through, by measuring their electrical resistivity.
- Elevation.**—A drawing or view of the vertical dimensions (side or front) of an object.
- Encoder.**—A device that combines color-hue and saturation information for transmission in color-television systems.
- Entrance Cone.**—The part of a wind tunnel from which air is drawn into the experimental chamber.
- Envelope.**—The glass bulb used in making electron tubes.
- Facing.**—(1) In construction, the use of a special aggregate in concrete, next to the forms, to give a desired finish. (2) Cutting on a lathe in a direction perpendicular to the longitudinal axis of the lathe.
- Fat Coal.**—Coal containing an excess of oily material.
- Fat-liquoring.**—Restoring fatty oils to chrome-tanned leather.
- Fat Sand.**—Sand with a high percentage of clay.
- Fidelity.**—In electronics, the degree of accuracy with which the output of a system reproduces the signal that is impressed on its input.
- Filler.**—(1) Material such as fiber glass or cellulose used to extend or improve the quality of a plastic when molded. (2) Any relatively fine material used between the particles of a coarser aggregate.
- Fining.**—Removing gas bubbles from molten glass by keeping the glass at a high heat.
- Fish Eye.**—In plastic molding, a small globular imperfection in the plastic material.
- Flash.**—A box-shaped container without a top or bottom used in the preparation of sand molds.
- Flash Point.**—The temperature at which a material vaporizes and can be made to burn by applying a small flame.
- Flattening.**—In painting, laying a coat of paint with a dead surface.
- Fleshing.**—The process of removing adipose material from hides.
- Floating.**—The process of smoothing the surface of poured concrete slabs.
- Flocculator.**—A device for bringing together two or more liquids to form a liquid precipitate of a third substance.
- Flour.**—Finely ground rock or mineral substances.
- Flyback.**—The rapid return of an electron beam in a cathode-ray tube after its horizontal sweep.
- Flying Conveyor.**—An overhead conveyor used to move parts from one operation to another and for temporary storage in a production-line operation.
- Forge.**—See FORGE, FORGING, AND FORGING MACHINES.
- Fork Truck.**—A small truck with prongs for lifting packages or pallets, used to move materials in warehouses or industrial plants.
- Fourdrinier Wire.**—The wire screen onto which pulp flows at the beginning of paper processing. Water is drawn through the screen by gravity and suction, leaving the fibers on top to knit together and form paper.
- Fractionating (Fractional Distillation).**—Removing the individual chemicals in a heterogeneous mixture by boiling each off at a different temperature and then condensing it.
- Frame.**—(1) A single complete sweep of the face of a cathode-ray tube. (2) In moving pictures, one of the series of pictures on a film.
- Free Volume.**—In the electrical lattice of a material or liquid, the holes which allow comparatively free movement of molecules.
- Frog.**—A kind of track intersection that allows flanged wheels rolling on one rail to cross another.
- Fuller.**—A round-edged blacksmith's tool used for spreading hot metal.
- Fuller's Earth.**—A high-water-content clay. See FULLER'S EARTH.
- Fulling.**—A textile-finishing process that shrinks fabric to give it a compact look and feel. Also known as felting or milling.
- Fundamental Research.**—The search for knowledge in a particular scientific area without regard to specific ultimate applications of the knowledge.
- Furnisher Brush.**—In textile operations, a device to feed color to printing rollers.
- Gad.**—A metal spike used to break up ore.
- Gang.**—Several cutting tools set up to make a variety of cuts simultaneously, as in gang milling or gang drilling.
- Gas Oil.**—A distillate from which diesel and light heating oils are made.
- Gathering.**—In glassmaking, the method of coiling the molten glass on the end of an iron tube preparatory to the work of blowing.
- Getter.**—A barium device placed in vacuum tubes to remove undesired gases. Once the tube is evacuated, the getter is heated to red heat (flashed) by high-frequency bombardment. The vaporized barium condenses and attracts undesirable gases.
- Gin Pole.**—A vertical guyed pole used with a block and tackle for lifting heavy weights.
- Glory Hole.**—(1) A small furnace used to reheat glass during its manufacture. (2) An open pit from which ore has been removed.
- Gob.**—A measured amount or lump of plastic or molten glass, usually the exact amount needed for a mold.
- Grab Set (False Set).**—Concrete rapidly developing a hard surface before its internal portions have solidified.
- Gravity Meters.**—Devices used in oil and ore prospecting to detect minute changes in gravity due to heavy rock structures near the surface.
- Gray Goods.**—Cotton cloth before it goes through finishing operations. Cloth sold in this form is "in the gray" (or greige).
- Gray Iron.**—The ordinary commercial iron often used in casting. It has very low tensile strength and little ductility. See also IRON—3. *Cast Iron; 11. Iron and Steel, Metallurgy of.*
- Grid.**—A fine wire screen that retards or encourages electron flow in a vacuum tube.
- Grout.**—(1) To fill small joints of masonry with a sandy cement. (2) The cement itself.
- Gun Metal.**—An alloy of copper and tin once commonly used to make cannons. Now any of various alloys used to imitate this metal when black or tarnished.
- Gusset Plates.**—Plates used in metal construction to join or strengthen members.
- Gyratory Crusher.**—A rock crusher which uses a large, vertical, conical shell driven within an enclosure by eccentrics.
- Harness.**—(1) In electrical manufacture, a large number of individually insulated wires worked together into a cable to make electrical contact between a number of points in the circuit. (2) The apparatus in a loom that shifts the warp threads alternately to form the shed.
- Head.**—(1) The pressure exerted by a fluid. (2) The distance from any lower plane up to the surface of a body of water.
- Headframe.**—The framework at the head of a mining shaft, used to raise and lower men and materials from and into the mine.
- Heat.**—A complete cycle of charging, melting, and pouring off metal in a furnace.
- Heterodyne.**—In radio, the action of two alternating

- currents of different frequencies in the same circuit. Being alternately additive and subtractive, they produce two-beat frequencies that are the sum of and difference between the two original frequencies.
- Hole Current.**—The electric current in a semiconductor. The name derives from the apparent holes in the electron distribution of a semiconductor.
- Horizontal Integration.**—The process in which a company acquires other institutions at the same distributive level, that is, a fabricator acquiring another fabricator.
- Horn.**—In electronics, a device to transmit an electromagnetic or acoustical pattern in a desired direction without the dispersion of signals common to other antennas.
- Hot Car.**—The vehicle that carries coke from the by-product oven to quenching and to storage near blast furnaces.
- Hot-top Ingot.**—An ingot cast in a mold with top extended to provide extra metal as the ingot cools and thus prevent a cooling cavity from forming in the top of the ingot proper.
- Housing.**—A structure encasing a part or subassembly.
- I Beam.**—A girder with an I-shaped cross section.
- Idler.**—A gear that neither drives nor is driven by a shaft to do useful work. It is used to make the final gear in a train rotate in the proper direction.
- Ignitron.**—An electron tube of the mercury-arc type using a mercury pool as a cathode and special igniter rod(s) as the anode. See also **ELECTRONICS—Diodes.**
- Image Orthicon.**—The tube commonly used as a pickup tube in television cameras. See also **TELEVISION—2. Engineering (Pickup Tubes).**
- Imbibition.**—In color photography, the transfer of a dye from a matrix to a prepared support.
- Impact Mill.**—A type of grinding machine that reduces material by pounding it with rows of loosely hinged hammers.
- Implosion.**—The inward shatter of a glass bulb under vacuum.
- Incongruent Compound.**—A compound that dissociates when melted and forms a new crystalline phase different in composition from the original material.
- Indirect Cost.**—The semivariable element in overhead cost. Indirect costs usually vary with production but not in direct proportion to it.
- Induction Field.**—The magnetic field set up around a conductor when a current passes through it.
- Induction Heating.**—Heating by inducing a current in a dielectric material that dissipates energy. See also **ELECTRIC FURNACES—Induction Furnaces.**
- Infra-audible Sound.**—Sound having a frequency below the lower pitch limit.
- Initial Set.**—Concrete or similar plastic materials when they first begin to crystallize and stiffen perceptibly. The initial set of a material may enable it to support its own weight but not added loads, which are put on only after final setting has hardened the material throughout.
- Insert.**—A metal device embedded in concrete, but exposed at the surface for use as a connection.
- Interlace.**—The pattern made by a television cathode-ray tube electron beam scanning alternate lines as it moves vertically down the screen, then scanning a second time to cover the alternate lines skipped the first time.
- Intermediate Frequency.**—In electronics, the frequency of a mixer output signal that is equal to the difference between the frequency of the antenna signal and the frequency of a local oscillator.
- Inverse Voltage.**—Counterelectromotive force.
- Inversion.**—The alteration of dextrorotatory cane sugar into levorotatory fruit sugar through the action of dilute acid. The product is termed "invert sugar."
- Inverter.**—A device for converting alternating current to direct current.
- Investment Casting.**—A process of casting metal in a ceramic or plaster-of-paris mold. The mold is made from wax patterns removed from the mold or investment by heat. The process holds extremely fine tolerances and surface finishes.
- Ion Burn.**—A discoloration of the face of a cathode-ray tube caused by bombardment of heavy negative ions.
- Izod Test.**—A pendulum type of impact test.
- J Box.**—In textiles, a bin used during the desizing operation. The J shape of the bin allows slow treatment of the cloth, along with a rapid yardage input and output.
- Jack Star.**—A hard metal piece used as an abrasive in tumbling.
- Jacking.**—A method used in installing conduits. A hole slightly larger than the pipe size is dug at the head of the pipe, which is then forced into the hole by horizontal jacks.
- Japanning.**—A process for covering sheet metal with a thick baked-on coat of oil or varnish.
- Jedding Ax.**—A kind of stonemason's ax whose head has one flat face and a pointed back or peen.
- Jenny Winch.**—A small derrick usually made of wood and operated by a small motor or by hand.
- Jetting.**—Sinking piles by digging out the earth beneath them with a water jet.
- Joint Costs.**—Costs common to the production of two or more end products, usually indirect and not identifiable as specific costs of any single end product.
- Joist.**—In construction, a beam to which a floor, wall, or ceiling is attached.
- Jumper.**—A wire used to bring current directly from a power source to a unit which usually has a switch or other component between it and the source.
- Jungle.**—The section of the production line where auto bodies are subassembled, so called because of the maze created by spot-welding wires and supports.
- Kelly.**—The uppermost link in the hollow shaft extending from the surface of the ground to the rotary bit used for oil drilling. It is square shaped to fit into the driving mechanism that turns the rotary bit.
- Kerf.**—The narrow slot made by the saw blade in sawing lumber.
- Kerogen.**—Oil shale.
- Keuper.**—Copper-bearing shale.
- Kidney Ore.**—Hematite occurring in compact masses shaped like kidneys.
- Kier Boiling.**—Boiling cloth in a weak alkaline solution under pressure for the purpose of removing grease, oil, or other natural impurities from it before finishing.
- Killed Steel.**—Steel deoxidized so that there will be little evolution of dissolved gases during cooling and hence few blowholes.
- Kinescope.**—A television-receiver cathode-ray tube.
- King Truss.**—A truss with a vertical post at its center.
- Kip.**—A unit (1,000 pounds) used in measuring stress.
- Klystron.**—A velocity-modulated electron tube used in high-frequency circuits. See also **ELECTRONICS—Microwave Electronics.**
- Lag Screw.**—A heavy screw with a square bolthead.
- Laid Up.**—Indicating that a dolly bar is tight against the rivet head prior to riveting.
- Lap.**—A flat compressed sheet of cotton as it comes from pickers.
- Lath.**—A structural material used as a base for plaster or stucco.
- Laundry.**—A trough or channel for conducting molten metal or a mixture of tailings and water.
- Lay.**—In textiles, the number of layers of material spread out and piled on top of each other for simultaneous cutting.
- Laying Out.**—Sewing together pieces of gray cloth into long continuous pieces for finishing.
- Leach.**—To dissolve materials out of a heterogeneous mix by slow action of a fluid.
- Lehr (Leer).**—A continuous oven for cooling glassware slowly.
- Lewis.**—A dovetailed steel instrument inserted into a corresponding mortise and used in lifting stone.
- Lift.**—In quarrying, a plane approximately parallel to the quarry floor along which quarry stone is usually split.
- Lime Glass.**—A glass that derives its amber color from lime in the processing batch.
- Linear Programming.**—A mathematical problem-solving technique for finding an optimum solution to a mathematical model involving many possible input and output variables.
- Link.**—In surveying, a unit of measurement (7.92 inches) derived from the link in a surveyor's chain.
- Lintel.**—In construction, a horizontal beam carrying a load across a wall opening.
- Live Load.**—A noncontinuous or variable stress which outside factors induce on a mechanical member or system.
- Load.**—(1) In electronics, the element to which transmitted signal power is delivered. (2) In mechanical design, a stress acting on a member or system.
- Lock Nut.**—A thin auxiliary nut screwed down upon an ordinary nut to prevent its loosening.
- Loss Factor.**—A measure of the rate at which heat is generated in a dielectric.
- Lost-wax Process.**—A casting method using a wax pattern that is subsequently melted from the mold, leaving a cavity with all the details of the pattern.
- Lug.**—A projection for holding or supporting something.
- Lump Lime.**—Quicklime as it comes from the kiln.
- Lute.**—(1) A fire clay mixture used to seal cracks in furnaces. (2) To seal with clay or other plaster materials.
- Macadam.**—A road surfacing. See **MACADAM.**
- Magna.**—See **MASCALITE.**
- Magnetic Head.**—A transducer for converting magnetic to electrical variations.
- Magnetic Lens.**—An arrangement of coils and magnetic components for focusing an electron beam.
- Magnetron.**—A kind of vacuum tube often used in high frequency applications. The magnetron functions un-

- der the joint action of an externally applied magnetic field and the field between its own anode and cathode. See also **ELECTRONICS—Microwave Electronics**.
- Maltha**.—A highly viscous asphalt petroleum that hardens quickly when exposed to air.
- Manganin**.—An alloy of copper, nickel, and manganese, used for electrical resistors.
- Maser (Microwave Amplification by Stimulated Emission of Radiation)**.—A device that reinforces radiations emitted by molecules and sets up strong controlled microwave oscillations. The result is an extremely narrow-range, stable frequency emission for use in electronic controls or amplifiers.
- Massacuite**.—The mass of sugar sirup and crystals obtained in sugar processing after crystallization.
- Matrix**.—The mixture of binding material and/or aggregate by which a larger aggregate is held in place.
- Memory**.—That section of a computer which holds information for later use. See also **COMPUTERS—2. Digital Computers, 4. History**.
- Memory Core**.—A small magnetic device in the buffer unit for the memory system of a computer. It stores electrical information as a single unit charge.
- Micarta**.—An electrical insulating material made of mica and paper.
- Mode**.—The actual mineral composition of a rock, as opposed to its theoretical composition.
- Modulation**.—The process by which one wave (the carrier) is varied in accordance with another (the modulating wave). In wireless transmission, modulation can be obtained by varying the carrier amplitude (AM), the carrier frequency (FM), or the carrier phase.
- Module**.—(1) In electronics or mechanics, a complete component unit of a total system which can be built or switched into the system as needed. (2) In hydraulics, a device for delivering or measuring a definite quantity of fluid.
- Molecular Electronics**.—A field of electronics that utilizes materials with extremely thin sections to take advantage of the electrical amplifying, resistance, and storage capacities of certain molecules.
- Moment**.—See **MOMENT**.
- Monkey Chatter**.—In radio, the sound resulting from cross modulation of side-band radiations from a strong adjacent channel and the signal of the desired frequency band.
- Monochrome**.—In television, the standard black and white picture image.
- Monte Carlo Method**.—A technique for mathematical problem solving which involves simulating the process under study by means of a model constructed from random numbers. See also **OPERATIONS RESEARCH—Techniques**.
- Morsing**.—Cutting square or rectangular holes in wood, usually for the purpose of making a joint.
- Mottle**.—A mixture of colors or shades to give a complicated pattern of specks, spots, or streaks.
- Mount**.—The assembly containing all the electrical and structural elements within the bulb of an electron tube, including cathode, heater, getter, deflection plates, ceramic separators, and lead wires.
- Muck Iron**.—The lowest grade of wrought iron.
- Mud**.—The chemically treated clay solution used to lubricate oil-drilling bits and to carry waste materials to the surface. Mud also plasters the wall of a well to keep its sides from caving in when the drill is withdrawn.
- Negatron**.—A four-element vacuum tube with negative resistance characteristics.
- Neoprene**.—See **CHEMICAL INDUSTRIES—Synthetic Rubber; RUBBER, SYNTHETIC—Neoprene**.
- Nesting**.—Packing units one inside the other to save space in shipment.
- Nipple**.—A short piece of pipe having a thread cut on the outside surface, used for joining sections of pipe together.
- Noble Gases**.—The inactive gases characterized by a complete outer (or sub) shell of electrons.
- Noise**.—Undesired interference with the intended electrical signal in a circuit. See also **ELECTRONICS—Amplifiers**.
- Oiling Off**.—Applying neatsoft or other oils to hides to make them pliable and soft.
- Opener**.—A machine which tears apart, loosens, and fluffs up cotton fibers before their processing into yarn or thread.
- Optical Comparator**.—A device for measuring the accuracy of a generated surface shape by projecting its magnified silhouette on a translucent screen containing an accurately enlarged pattern of the desired shape.
- Oscillator**.—Any device that generates oscillations, but particularly the device for generating the high frequency carrier signal for radio or television communications.
- Oscilloscope**.—A device for determining the amplitude, timing, and shape of electrical pulses by displaying their characteristics on the face of a cathode-ray tube.
- Packing**.—Any material used to obtain a fluid-tight seal between mating parts that move relative to one another.
- Pad**.—(1) A mangle used to apply dyestuffs to fabric. (2) A device for attenuating electrical signals.
- Palletize**.—To prepare materials on low, flat wooden racks called pallets. Sometimes this enables shippers to obtain lower freight rates because of simplified handling.
- Paneling**.—Impressing rings into the end of a cylindrical can to increase its strength.
- Parkerizing**.—Applying a protective iron phosphate coating to iron or steel.
- Peaking Circuit**.—In television, an electrical circuit to extend the frequency response of the video amplifier.
- Phantom Freight**.—Charges for hauling freight over distances not actually covered; the difference between freight cost from the basing point to the consumer and the lower actual freight from the producing mill to the consumer.
- Phenolics**.—Plastics normally derived from the reaction of phenol with an aldehyde. One of the most common plastic bases, it normally forms a thermosetting plastic.
- Photocell**.—An electron tube activated by light or other radiations. The complete photocell circuit and apparatus usually measure the radiation or use it as a signal to operate some other device.
- Picking**.—Opening and cleaning textile fibers and forming them into continuous mats preparatory to spinning.
- Picks**.—(1) The number of filling threads per inch in a woven fabric. (2) The speed at which a shuttle weaves filling threads in a particular cloth.
- Pickup**.—In electronics, a device for converting sound, picture, or other intelligence into electric signals.
- Pig**.—Metal as it is initially cast for marketing.
- Pig Iron**.—See **IRON—4. Pig Iron**.
- Pitot Tube**.—A device for measuring the velocity head of water by seeing how high above its surface water will rise into a special orifice. See also **ANEMOMETER**.
- Plasticizers**.—High-boiling liquids added in plastic manufacture to make molecules flow more easily during molding or forming.
- Plat**.—A scale diagram of a land area showing boundaries but not its cultural or relief features.
- Plate**.—That part of an electron tube which attracts electrons when it is positively charged.
- Polarization**.—The process by which vibrations of light or other radiations are confined to one plane. See also **POLARIZED LIGHT**.
- Poling**.—In metallurgy, the reduction of copper oxide in molten blister copper by inserting a green wood into the liquid.
- Pore Volume**.—The empty space between bits of cemented abrasive in a grinding wheel.
- Porgie**.—The raw material, largely menhaden and offal, from which fish oil is extracted.
- Pot**.—In electronics, a potentiometer.
- Poteye**.—In textiles, a hole through which cloth passes to form it into a loose rope for easy handling during finishing operations.
- Powder Metallurgy**.—The process of using finely divided metal powders to make useful articles. The process involves pressing particles into intimate contact and then sintering them into solid shapes. See also **METALLURGY—5. Physical Metallurgy**.
- Preforms**.—In plastic molding, loosely compressed powder in the size and shape to be introduced into the mold.
- Primary Coil**.—In electricity, the wire winding through which the inducing alternating current is sent.
- Programming**.—The process of arranging information and computer circuitry so that the computer can manipulate information as desired.
- Prony Brake**.—A device for measuring mechanical horsepower. See also **DYNAMOMETER**.
- Proration Laws**.—Laws that govern the amount of oil that may be produced in a state. Their purpose is to stabilize prices, prevent chronic oversupply, and avoid rapid uneconomic exploitation of new oil discoveries.
- Puddling Furnace**.—A furnace in which cast iron is converted into wrought iron.
- Pugmill**.—The mill for mixing and kneading clay in brick or earthenware manufacture.
- Putrefaction**.—In chemicals, the decomposition of organic materials under conditions of oxygen deficiency. This results in ill-smelling gases.
- Putting Up**.—In textiles, cutting cloth into shorter lengths after finishing and preparing it in rolls, bolts, or folds, according to customer specifications.
- Pyrometer**.—A device for measuring high temperatures by means of thermoelectric current, the expansion of

- gases, and the intensity of light radiations.
- Quick Make.**—A special spring device on a switch or circuit breaker for high-speed contact closing.
- Radiography.**—Photography using high-energy particles, instead of light, to activate the sensitive plate.
- Rasper.**—A machine for breaking up chemicals that have blocked or hardened.
- Raster.**—In television, a complete pattern of scanning lines on a cathode-ray tube.
- Rate Base.**—The investment upon which regulating commissions allow public utilities a predetermined percentage of profit return.
- Rat Race.**—A hybrid ring junction of wave guides.
- Recalcence.**—A phenomenon in which iron or other ferromagnetic materials temporarily heat and expand of their own accord during the cooling process.
- Reciprocity.**—The practice of buying from a customer in order to obtain trade advantages in selling to him (or vice versa).
- Red Dog.**—A red-colored ash residue resulting from the combustion of waste coal products.
- Red-hardness.**—The hardness of a metal when it is at red heat.
- Reducing.**—(1) Removing oxygen from a compound. (2) Removing nonmetallic elements from impure metal or metallic ores.
- Regenerating Furnace.**—A furnace in which the heat of the waste gases is used to heat the incoming air blast. Where gas is used for fuel, this also is heated by the hot waste.
- Regenerator.**—In oil processing, a unit for ridding a used catalyst of chemical contaminants that it may have picked up.
- Reinforced Concrete.**—See CONCRETE.
- Repressuring.**—Pumping water or gas into an oil reservoir to restore pressure as the oil is depleted.
- Retort.**—A container in which a chemical reaction can take place under controlled pressure conditions.
- Riprap.**—An irregular arrangement of stone or other materials in a wall to prevent water from washing out the soil behind it.
- Rocker.**—In construction, a support for the free end of a bridge or truss. It allows the structure to expand or contract without building up internal stresses.
- Roving.**—The process of reducing textile slivers to suitable size for spinning. Slivers are passed through rollers and wound on bobbins, and in the process the fibers are given a slight twist. See also TEXTILE MACHINERY.
- Runner.**—The main revolving part of a hydraulic-reaction turbine, including the hub and blades.
- Safety Factor.**—The ratio of the working strength of a member to the actual stress to which it will be subjected.
- Samming.**—Adding uniformly distributed moisture to hides by packing leather in sawdust and storing it under proper conditions.
- Sanforizing.**—A patented, controlled shrinking process designed to reduce the potential shrinkage of textile fabrics to less than 1 per cent.
- Scabble.**—In stonecutting, to dress roughly with a hammer.
- Scale Breaker.**—A metal-rolling mill with special rolls to break the scales from ingots. The broken scale is then blasted away by jets of water.
- Scanning.**—The process by which an electron beam traces out its information on the face of a cathode-ray tube.
- Scray.**—In textiles, a trough through which cloth passes.
- Screed.**—A board used to level off concrete.
- Screw Machine.**—An automatic turret lathe having an automatic through feed for bar stock, and often having multiple spindles to allow several simultaneous machining operations.
- Scrolling.**—A method of cutting strips of tin plate to minimize the waste material between the circles punched out for ends of cans.
- Scuff.**—Material that flakes off the surface of a metal; dross.
- Sealing In.**—Fusing the bulb and mount of an electron tube.
- Seconds.**—Products which do not meet the quality standards of the plant, but are sold on the open market at a reduced price.
- Seismic Survey.**—The process of determining geological characteristics of subsurface structures by planting an explosion and recording the pattern of returning shock-wave echoes. It is commonly used in ore and oil prospecting.
- Selsyn.**—A device for transferring mechanical displacement to a distant point; a portion of a servomechanism.
- Semiconductors.**—Electrical conductors having a resistivity at room temperature between that of metals and insulators; characteristically, their electrical carrier concentration increases with temperature over some temperature range. See also ELECTRONICS—*Diodes*.
- Shaving.**—In leather processing, cutting away the extra thickness of skin along the backbone line of a hide.
- Shrink Mixing.**—Completing the mixing of concrete in a truck mixer after the ingredients have been stirred together initially in a stationary mixer.
- Shrinkage.**—Production units lost because of production errors.
- Sill.**—A timber laid flat to support a structure.
- Singeing.**—Passing cloth rapidly through gas flames to burn off fuzz, lint, and loose threads.
- Skelp.**—An iron or steel strip from which rods or tubes are made by bending and welding.
- Skewback.**—In construction, the first or bottom stone in the curving section of an arch. It has a horizontal base and sloping top surface.
- Skid.**—A strong metal and wooden pallet serving as a base on which heavy machinery or materials can be dragged.
- Skin-dried Molds.**—Sand molds whose metal contact surfaces are specially hardened to withstand the heat and pressure of molten metal better than green sand does.
- Skip Cars.**—Vehicles for hoisting iron ore, coke, and limestone to the top of blast furnaces.
- Skull.**—The film of metal or dross remaining in a ladle after the metal has been poured off.
- Sky Wave.**—That part of the energy radiated from an antenna which does not follow the earth's curvature but goes upward to be reflected or partially absorbed by the ionosphere.
- Slagging.**—The process of covering a test spoon with slag before sampling the metal in a heat.
- Slake.**—To make lime crumble by contact with water.
- Sleeve.**—A hollow tube of soft metal into which a rod or bar is inserted. It is similar to a bearing, but not intended to withstand the friction of continuous rotation.
- Sley.**—The number of warp threads per inch in a woven fabric.
- Slip Casting.**—Making earthenware by casting fluid clay.
- Sliver.**—A soft rope of textile fiber as it comes from carding prior to spinning.
- Slops.**—The sludge left after a chemical process.
- Slurry.**—A thin watery mixture carrying minerals in a chemical process.
- Snag.**—To remove the unwanted parts of a casting by rough grinding.
- Snatch Block.**—A special block used in hoisting or pulling. It has an easily opened side for quickly connecting rope.
- Snow Cat.**—A caterpillar-tracked car or truck used to work in snowy areas where removal of snow is not feasible.
- Sole Plate.**—A plate fastened to the bottom of a beam or truss to serve as a bearing plate on masonry.
- Solidus.**—The temperature below which a material is completely solid.
- Souring.**—In leathermaking, the treatment of leather with weak organic acids, to remove stains and to bleach the surfaces preparatory to dyeing.
- Spacer.**—A casting, usually spool shaped, used to separate girders in a structural member.
- Spaghetti.**—Insulated sleeving used on thin wires in electronic assemblies.
- Spinnerets.**—Devices with small holes through which liquid synthetic-fiber materials are forced in spinning threads of the fiber.
- Spinning.**—In metalworking, forming round hollow ware by pressing sheet metal into a mold revolving on a lathe.
- Splitting.**—Dividing hides into two or more layers of uniform thickness for leather manufacture.
- Spooler.**—A machine to wind the contents of several bobbins into a longer continuous length called a spool.
- Spot.**—A commodity bought or sold for immediate delivery.
- Sprue.**—A hole through which molding material is poured into the gates of the mold and thence into the mold cavity.
- Stadia.**—A method (or the equipment) used to determine distances in surveying by observing the space on the rod scale intercepted by hairlines on the telescope.
- Staking.**—A process by which leather is softened by pulling and kneading.
- Stand.**—(1) A mill used to roll blooms, slabs, or billets into semifinished or finished shapes. The terms "two high," "three high," and so on, indicate there are two, three, or more rolls in the stand. (2) Three or four lengths of drill pipe used in oil drilling. The drill pipe is removed in stands to replace or repair a worn drill.
- Steeping Pits.**—The bins in which cloth is stored while a desizing solution dissolves entrapped starch.
- Sticker.**—(1) A machine to mold and shape wood stock parallel to the grain. The sticker usually has four rotating cutter heads, one for each surface. (2) A piece of material used to separate pieces of lumber in storage.
- Stirrups.**—In construction, U-shaped bars used in rein-

- forcing concrete beams against shear or diagonal stress.
- Straight-run Gasoline.**—A condensate of vapor from crude oil boiled off at 90° to 410° F.
- Stratigraphic Trap.**—One of several common geological formations which form natural traps for oil. It occurs when one rock stratum bows upward at its edges to form a natural bowl to trap liquid subsurface oil.
- Straw Boss.**—A person, usually a subforeman on a work crew, who takes responsibility during frequent absences of the foreman.
- Stretch.**—In masonry, a stone with its greatest length parallel to the direction of the wall.
- Stria.**—Surface or internal threadlike inhomogeneities in transparent plastic.
- Stringer.**—(1) A longitudinal member of a bridge used to support the roadway over it. (2) A beam directly supporting the floor of a structure.
- Stripping.**—(1) Removing molds from ingots. (2) Removing the top layer(s) of soil to work the mineral deposits below. (3) Tearing or breaking off the threads of a screw or the teeth of a gear.
- Stumpage.**—Money paid an owner for standing timber.
- Subpunch.**—To punch a rivet hole smaller than the rivet size so that the weakened metal can be removed by reaming before riveting.
- Sump.**—A hole or well into which water may be directed to drain an area.
- Sun Ray.**—A semiglossy finish generally applied to the inner sides of aluminum ware.
- Supercharger.**—A device to compress air before it enters an internal combustion engine for the purpose of improving the efficiency of the engine.
- Superelevation.**—In roadway construction, the height by which the high side of a banked roadway curve exceeds that of the lower sides.
- Superfinishing.**—An abrasive process that removes small particles of metal and minute surface imperfections after ordinary machining operations.
- Surge Tank.**—A liquid-holding tank used to absorb irregularities in fluid flow.
- Surplus.**—All accumulated profits from operations not specifically reserved for a particular use.
- Swell.**—The increase in volume between excavated grading material in its natural state and the volume of the same material in an embankment after it settles.
- Swing.**—One method of describing lathe size. The term refers to the maximum diameter (in inches) of an object that can be rotated without interference over the bedways or compound rest of the lathe.
- Sync Signal.**—The signal employed to synchronize a cathode-ray tube's scan timing with that of some outside signal source or output.
- Tackle.**—An arrangement of rope and blocks used to move or lift heavy loads.
- Tag Line.**—A light wire or rope used to keep a bucket from twisting as it is hoisted.
- Tailings.**—Rejected matter, such as stones that do not pass through the largest screen after crushing.
- Tapping.**—(1) Releasing molten metal from a furnace. (2) Cutting an internal (female) thread.
- Teeming.**—Pouring molten metal into ingot molds.
- Telemeter.**—A device for or the process of measuring phenomena at a distance and transmitting the measurement information to a collection point by radio, telegraph, or television.
- Telpher.**—An electric hoist operating on an overhead track.
- Tenderness.**—The relative resistance of a material to localized stress as at corners, bends, holes, or flex points.
- Tenoner.**—A machine used to form and shape wood at right angles to the grain, particularly to make tenons for joining.
- Tenter.**—In textiles, a machine for drying cloth over a long flat frame. It is used before printing cloth to make sure that threads are in proper squared position.
- Terneplate.**—A ferrous metal sheet covered with a lead-tin alloy and cast in a hot-dip process.
- Test Pattern.**—A video signal transmitted over the air or in a closed-circuit system to test television receivers and/or transmitting equipment.
- Thermal.**—Any device using the electromotive force developed by holding the two junctions of a two-metal circuit at different temperatures; a thermocouple.
- Thermionic Emission.**—A phenomenon in which electrons or ions are boiled off by an emitter when it is heated.
- Thermos-bottle Car.**—A vehicle to transport molten pig iron from the blast furnace to open hearths.
- Tie.**—(1) A tension member of a truss. (2) A surveying term for measurements made to locate the position of a remote point by reference to points of known position.
- Tipping Off.**—Closing off the exhaust of an evacuated electron-tube bulb.
- Tocco Process.**—A method of hardening the surface of steel by induction heating.
- Toggle Joint.**—A mechanism consisting of two bars joined end to end but not in line. When pressure is applied at the point where they are joined, the mechanism tends to straighten out and exerts a strong horizontal pressure if confined.
- Tooled.**—A finished surface made by dressing leather with a brush hammer or crandall.
- Top Pressurization.**—A process in which blast furnaces, instead of being open at top, are sealed and air is forced through under pressure to increase the furnace yield.
- Torpedo.**—(1) A spreader that forces molded material against the walls of the mold cavity. (2) An explosive charge used to clear obstructions in an oil well.
- Townsend Avalanche.**—An effect produced when one ion creates others by collision and these in turn create more ions, resulting in cumulative ionization.
- Tracer.**—A foreign substance, usually a dye or radioactive element, introduced into a dynamic system to see how the system is performing.
- Train.**—A series of metal-rolling stands placed close together for continuous rolling of sheet metal. Several mills in a train normally contact the metal strip simultaneously.
- Transducer.**—A device by which energy from one transmission system can flow to another. Often the input and output energies are of a different form, as electrical to acoustical.
- Turbohearth.**—A steelmaking furnace similar to the Bessemer, in which air is blown over the metal surface rather than through it.
- Tying In.**—In textiles, tying threads of a new beam onto those of the old beam when it runs out.
- Universal Grinder.**—A grinder that usually can finish flat, round-external, round-internal, and special-form surfaces.
- Universal Joint.**—A fastening that allows the connected shafts to move in both vertical and horizontal planes while rotating.
- Venturi.**—A gradual restriction in the opening of a hydraulic tube, used to measure fluid velocity.
- Vertical Integration.**—The process of a company's growth by acquiring (1) distributive operations closer to the consumer (forward integration), and/or (2) production operations that give it greater control over its raw materials or fabricated parts (backward integration).
- Vinyls.**—Plastics derived by polymerizing a vinyl ($\text{CH}_2\text{CH}-$) compound. They are among the most common plastic bases, usually forming thermoplastic material.
- Viscosity.**—See VISCOSITY.
- Vitrification.**—The consolidation or incipient fusion of material into a glassy mass under the influence of intense heat.
- Voder.**—An instrument for the synthetic production of human speech.
- Wafer.**—In electronics, a flat ceramic part on which circuits can be printed. Wafers are joined together to form complete sections (called modules) of electronic circuits.
- Water Cushion.**—The pool of water at the foot of a dam spillway. Its purpose is to break the force of the water coming over the dam.
- Wattles.**—Bundles of brushlike material used in erosion control on steep slopes.
- Wave Guide.**—A device for conducting high frequency electrical energy. It consists of carefully dimensioned hollow conducting tubes through which energy flows.
- Waybill.**—A paper that accompanies goods in transit. It describes the goods and gives all shipping instructions pertaining to them.
- Web.**—(1) The section of a girder or I beam between the flanges. (2) The relatively thin sections of metal used to separate and support the major stress-bearing parts of a cast-metal part.
- Weep Holes.**—Openings left in retaining walls, abutments, and aprons to relieve pressure by allowing water to drain through.
- Wildcatting.**—Drilling for oil in areas where there are no proved reserves.
- Woof.**—The crosswise interlaced strands in woven fabric; the weft.
- Wringing Fit.**—A metal-to-metal, shaft-to-ring fit with no negative allowance. The shaft must usually be inserted under slight pressure.
- Yagi.**—A television antenna array usually consisting of parallel driven element(s) plus parasitic elements. It is used for reception where the signal is weak.
- Yankee dryer.**—A large steam-filled drum used as the first stage in the process of drying paper after the pulp fibers have been initially pressed together.

INDUSTRIAL VOCATIONAL TRAINING. See EDUCATION AND INDUSTRY.

INDUSTRIAL WORKERS OF THE WORLD (IWW), a labor organization of revolutionary character, with tenets similar to those of the syndicalists (see SYNDICALISM) which, in the early 20th century played an important part in labor history. The organization was founded at Chicago, Ill., in the summer of 1905, its chief component body being the Western Federation of Miners. Established in opposition to the craft unionism of the American Federation of Labor, by such men as Eugene V. Debs, Daniel De Leon, and William D. Haywood, the IWW had as its objective the overthrow of capitalism by socialism. The issue of political action led to the withdrawal in 1908 of a group under Daniel De Leon, who organized a rival IWW, which was later known as the Workers' International Industrial Union. Although it came to be represented in Canada, Australia, and, to a slight degree, in Europe, the IWW's chief strength was in the United States. Members, known as "wobblies," included lumber and mining workers in the west, wheat workers in the central states, textile workers in the east, and dock workers in port cities. Peak membership was reached in 1912, when the organization numbered about 100,000 members. The IWW conducted 150 strikes, among them a strike of textile workers at Lawrence, Mass., in 1912; a strike of silk workers at Paterson, N. J., in 1913; and a strike of iron workers at the Mesabi Range in Minnesota in 1916. The IWW opposed World War I, and in 1918 Haywood, its national secretary and chief organizer, and various other members were convicted of sedition and imprisoned. Perhaps the most serious clash in which the IWW was involved was that at Centralia, Wash., on Nov. 11, 1919, when a riot ensued after a parade of World War veterans was fired upon from an IWW hall, with one of the members taken prisoner later being lynched. Among factors in the decline of the IWW were its activities during World War I and the severe penalties imposed, including public expressions of disapproval; and the rise of other organizations, among them the Communist Party and the Congress of Industrial Organizations.

INDUSTRIALISM, a term used to describe a social organization dominated by industries, particularly large-scale industries. See INDUSTRIAL REVOLUTION, THE; UNITED STATES—23. *Industry*.

INDY, an'dé', **Vincent d'** (in full PAUL MARIE THÉODORE VINCENT D'INDY), French composer: b. Paris, France, March 27, 1851; d. there, Dec. 2, 1931. He was educated by his grandmother, his mother having died while he was still young. During 1862-1865 he studied piano with Louis Diémer, and afterwards he studied harmony and theory under Antoine François Marmontel and Albert Lavignac. After serving in the Garde Mobile during the Franco-Prussian War (1870-1871), he studied composition with César Franck. He entered the Conservatory at Paris when Franck became professor of organ there in 1873 and continued his studies with him until 1880. During 1873-1878 he was chorus master and tympanist with the Concert National, founded by Édouard Colonne; and in 1871, together with Franck, Camille Saint-Saëns, and others, he

founded the Société Nationale de Musique. He served as the society's secretary until 1890, when he became president. Together with Félix Alexandre Guilmant and Charles Bordes, in 1894 he founded the Schola Cantorum, where he taught and, after 1911, served as sole director. In 1912 he became professor of the orchestra class at the Conservatory. His numerous compositions include *La Forêt enchantée*, a symphonic legend (1878); *Le Chant de la cloche*, a dramatic legend (1879-1883); *Wallenstein*, a symphonic trilogy (1874-1884); the lyric dramas *Fervaa* (1889-1895) and *L'Étranger* (1898-1901); *Symphonie Cévénole (sur un chant montagnard français; Symphony on a French Mountain Air 1886)*, for orchestra and piano; *Istar*, symphonic variations (1896); piano compositions; chamber music; and three symphonies. He was the author of several books, including *Cours de Composition musicale*, with Auguste Sérieyx (3 vols., 1903-1933); and biographies of Franck (1906) and Ludwig van Beethoven (1911; Eng. tr., 1913).

INE or **INI** (Lat., *INA*), West Saxon king: d. Rome, c.726. Son of Cenred, a West Saxon underking, Ine was chosen king of the West Saxons in 688, succeeding Caedwalla who had resigned the throne. Like his predecessor, he and his wife Aethelburh were of the royal line of Ceawlin. Following Caedwalla's example he invaded Kent to avenge the death of Mul, who was Caedwalla's brother, and probably his own uterine brother. King Wihtred of Kent in 694 paid him 30,000 pieces of money as wergild for Mul. The war gained Ine as well hegemony over all land held by the English south of the Thames, including East Anglia and Essex. A war in 710 extended his kingdom westward and it probably thereafter included part of Devonshire. His only brother Ingild, who died in 712, was the great-grandfather of Egbert (q.v.), first West Saxon king of all England. In 715 Ine defeated invading Mercians. Meanwhile, between 690 and 693 he published a series of laws, the earliest extant West Saxon legislation. Already London had been included in his domain. The laws indicate that Welshmen in the kingdom, who had accepted Christianity, were legally protected. It is supposed that Ine's mother was a Welshwoman, and Welsh legend assimilates him to the folk hero Ivor. After a 37-year reign Ine abdicated and with his wife Aethelburh made pilgrimage to Rome where he died soon after his arrival.

INERTIA, in-ûr'shâ, *in physics*, that property of a material body which tends to resist any change in its existing state of rest or motion. The concept of inertia provides the basis for Sir Isaac Newton's *first law of motion*, published in his *Philosophiæ Naturalis Principia Mathematica* (1687). The law states that a body at rest tends to remain at rest, and a body in motion tends to remain in uniform motion in a straight line (that is, without acceleration), unless acted upon by an external force. The force in question must overcome the inertia of the object in order that either the speed or direction of motion of the object will change.

Inertia is a function of the mass of the object (the quantity of substance it contains) and, in the case of a rotating object, the distribution of mass with respect to the axis of rotation. It is a commonly observed fact that—even with negligible friction, as in moving an object over ice, or on a

smooth film of oil—a greater force is required to set a heavy object in motion than a light one. The same situation applies to the force required to stop a heavier object, once under way. Mass thus provides a quantitative measure of inertia, but the effect of inertia is observable only when the object has been subjected to an acceleration.

If a pebble and a rock are both hurled into the air with identical force, the pebble travels faster and farther than the stone. The factor responsible for the observed difference is inertia. A heavy car will coast farther after the brakes are applied than a light one; a car traveling at fast speed can leap a ditch as if it were not there. The same inertial effects of mass, together with the associated concepts of *momentum* and *impact* (q.v.), also account for the greater damage done to a smaller car in collision with a larger one, even though the two cars are traveling at the same speed.

Conversely, inertia is responsible for the fact, as Galileo (1564–1642) first proved in his famous experiment on the Leaning Tower of Pisa, that a body of large mass and one of small mass fall at the same speed under gravity. According to Newton's law of gravitation (see GRAVITATION), a twenty-pound object exerts a gravitational force against the earth which is twenty times greater than that produced by a one-pound object, and if gravity alone is considered, the heavier object should fall twenty times as fast. However, the twenty-pound object also has twenty times as much inertia or resistance to velocity change under the force of gravity. Accordingly, the one-pound and twenty-pound objects fall with equal speed.

Inertia is that property which causes an object to fly off tangentially from rotation in a circle, as in the case of an object twirled about the head on a rope and then let go. Thus, if *centrifugal* force is thought of in its restricted physical sense as only a reaction to *centripetal* force, it is the balance between inertia and gravitational force which keeps the planets and other members of the solar system revolving in closed orbits about the sun, and the satellites about their planets.

In the case of a rotating object, the distribution of mass with respect to the axis of rotation is also important, and introduces the concept of *moment of inertia* (see MOMENT). Representative values of the moments of inertia for various solid figures are as follows (where R is the radius of the body or of its circular cross section, and M is its mass):

	Moment of Inertia, I
a. Solid sphere about any diameter	$\frac{2}{5} MR^2$
b. Solid cylinder or disk, about an axis through the center, and perpendicular to the circular cross section	$\frac{1}{2} MR^2$
c. Hoop or <i>thin</i> ring about any diameter	$\frac{1}{2} MR^2$
d. Hoop, <i>thin</i> ring, or hollow cylinder about an axis through its center and perpendicular to the circular cross section of the body	MR^2
e. Ring or annulus (inner radius R_1 , outer radius R_2) about an axis through its center and perpendicular to the circular cross section	$\frac{1}{2} M (R_1^2 + R_2^2)$
f. Solid disk about any diameter	$\frac{1}{4} MR^2$

Since inertia is that physical quality which provides the tendency for a moving object to coast even after the propelling force has been

removed, several interesting cases where rotation and translation (straight-line motion) occur simultaneously may be analyzed from the above table. It is an inviolable law of physics that as the value of I decreases, the speed of rotation increases. Thus if a ball, a disk, and a hoop, regardless of their individual masses and radii, are started rolling down a hill together, the sphere a will roll to the bottom first, because its value of I is smallest; it will be followed by the disk b , and finally the hoop d . The same three objects placed separately on light frictionless sleds will *slide* down the hill in equal periods of time, each faster than the ball will roll down. A heavier man will coast faster downhill on the same bicycle and with the same initial impulse than a lighter man, but if heavier tires or rims are substituted, the coasting speed will be decreased.

Because of the necessity in modern naval fire-control systems (see GUNNERY) to assure a stabilized reference free from the effects of roll, pitch, and yaw of the ship, the tracking coordinates for a target aircraft are usually referred to an *inertial* or space-fixed coordinate system, which, through gyrostabilization, is independent of deflectional influences produced by the motions of the vessel.

Similarly, since no point in the universe is at absolute rest, a set of coordinate axes fixed with reference to the average of the space motions of the stars and known as the *primary inertial* system or *fundamental standard of rest* is chosen by physicists and astronomers, with respect to which origin individual motions in space may then be more rigorously defined.

Certain relativistic concepts of inertia are also noteworthy. According to the theory of relativity set forth by Albert Einstein (1879–1955), since mass increases with velocity, inertia does also (see RELATIVITY—*Einstein's Relativity of Time and Space*). The value of inertia is therefore assumed in this theory to increase rapidly as the velocity of light, 186,282 miles per second, is approached. At this point, inertia is presumed to become infinite, so that continuous acceleration of the object to reach or exceed the velocity of light is impossible.

Program, The National Science Foundation.

INFALLIBILITY, ɪn-fəl-i-bil-i-ti, exemption from the possibility of error. The word is used as applied to arguments, statements, reasoning, or the formation of judgments.

The infallibility of the Roman Catholic Church means that the church cannot err in its judgments concerning matters of faith or morals. The seat of infallibility rests in the pope as successor to St. Peter (Matthew 16:18). In the acts of the Vatican Council held in Rome in 1869–1870, during the pontificate of Pius IX, the following is the text defining the nature of the infallibility of the pope:

"the Roman Pontiff, when he speaks *ex cathedra*—that is, when in the exercise of his office as pastor and teacher of all Christians he defines, by virtue of his supreme Apostolic authority, a doctrine of faith or morals to be held by the whole Church—is, by reason of the Divine assistance promised to him in blessed Peter, possessed of that infallibility with which the Divine Redeemer wished His Church to be endowed in defining doctrines of

faith and morals; and consequently that such definitions of the Roman Pontiff are irreformable of their own nature (*ex sese*) and not by reason of the Church's consent." The Orthodox Eastern Church and certain Anglicans maintain, with Roman Catholics, that Christ promised the true church infallibility.

Consult Toner, P. J., "Infallibility," *The Catholic Encyclopedia*, vol. 7 (New York 1910).

INFAMY and INFAMOUS CRIMES, in common law the first means disqualification from giving legal evidence as a result of having committed the second, the theory being that a person capable of such crimes is incapable of speaking the truth. Both in Great Britain and generally in the United States this disqualification has been abolished by statute, and previous convictions for crime have been considered to affect a person's credibility without impairing his legal capacity to give evidence. Infamous crimes are strictly those which entailed punishments. The fifth amendment to the federal Constitution speaks of "capital or otherwise infamous crime" and we read in Nathan Dane's *General Abridgement and Digest of American Law*, vol. 2, pp. 567-570: "Punishments clearly infamous are death, gallows, pillory, branding, whipping, confinement to hard labor and cropping." Infamous punishments include imprisonment in state prison or penitentiary with or without hard labor, and crimes which entail such punishments are undoubtedly to be considered infamous crimes, in the sense implied in the 5th Amendment to the Constitution.

INFANCY AND INFANT CARE. The human being from birth to about 12 months has received more and more study and attention in the past several decades. No other period of history has witnessed such great advances in research on how children grow and develop as has the last half-century. And increasing emphasis has been placed on the effect of what the individual experiences in infancy. The physical, mental, emotional, and social aspects of a child's life are coming to be seen as constantly interwoven, although we still speak of them separately.

The Newborn.—The infant who not so long ago was generally looked on as a "lovable bundle," with no particular ability to feel or think or react, is recognized today as a very impressionable being indeed. The newborn—weighing an average of about 7½ pounds, measuring about 20 inches in length (individual babies range from "very small" to "very large," and all are normal), often with too much or no hair, eyes that "float," an over-large head and stomach, and sometimes a mottled, reddish skin—may appear as something less than human and remarkably helpless. But he can cry, he can feel warm or cold, he can smell and taste, he can cough and sneeze, he can sense hunger pangs and the need to suck. Above all, he can feel loved or not. The skin of the newborn seems to be especially sensitive and he responds to contact, patting, and caressing. He senses whether he is being held snugly and firmly, or distantly and awkwardly. So the impulses parents feel to cuddle and protect the infant, to handle him gently, fit in precisely with his needs. Scientific study has shown that infancy passed in such a loving, warmly dependable environment has the best chance of resulting in secure, outgoing, and confident adulthood.

Feeding.—Along with new findings on *what*

to feed the infant have come important discoveries on *how* to feed him. Whether the baby's milk comes from breast or bottle, physical contact with his mother evidently adds to the satisfaction of feeding. Authorities in various fields of child development have at times insisted that the breast is the only satisfactory way of feeding an infant, and this has aroused a feeling of guilt and resentment in some mothers. The trend today is to recommend breast feeding within the framework of a mother's desires. A working mother, or one who cannot or for any reason does not wish to nurse, is not likely to have for her baby a love untinged with resentment if she *forces* herself to breast feed him. In addition, science has so perfected formulas for infants that there is no danger of a bottle-fed baby being undernourished. However, breast feeding is recommended wherever possible, since many physicians believe it offers an advantage to the baby, physiologically as well as emotionally, and because of the definite advantages that result from the mother's own satisfaction in nursing her baby.

Whatever the method of feeding, the baby needs affectionate handling, plenty of time, and a relaxed atmosphere, just as much as the milk itself. In the early studies of infants' needs, "self-demand" became a significant concept, its theory being that all infants differ in appetite or food needs, both as to quantity and as to time intervals.

In other words, infant hunger cannot be gaged by the clock. This theory was for a time misinterpreted by mothers and fathers anxious to be ideal parents, and many a baby found a bottle in his mouth almost every time he opened it. From this rather violent swing away from the old rigidity, there has been a settling down to a reasonable, commonsense self-demand principle. Infants who are fed when it is reasonable to think they are hungry (and not merely when they are crying—which they could do for a variety of other causes) have been found, in general, to work out a fairly regular feeding schedule of their own several weeks after birth.

Weaning.—The method used in weaning is another influential factor in a child's subsequent attitude toward food and toward people. The decision that a baby should be ready to give up breast or bottle at a certain time is now recognized as arbitrary, and each mother has to work out the weaning experimentally. In most cases, breast-fed babies can be introduced to bottle or cup at about seven or eight months. If a "relief bottle" has been used previously—that is, if from birth one feeding a day has been from the bottle—the process is usually easier, since the infant is already acquainted with this way of getting his food and also with the milk. But whether he is already acquainted or not, weaning must be a step-by-step procedure, beginning with substitution of one bottle feeding for one breast feeding for a few days, then another substitution for the next few days, and so on until he appears content to give up the breast entirely. Introduction to a cup for a bottle- or breast-fed infant should also be accomplished in the same leisurely fashion. The infant must have time to get used to the new taste and texture, to the lack of warmth in a rubber nipple or a cup rim, and to the distance from his mother's body.

Solid Foods and Self-Feeding.—When to introduce solid foods is a question to be settled by individual parents in consultation with the baby's physician. Some doctors recommend solids when

an infant is only a few weeks old, others prefer to wait until three or up to six months. The guiding principle, whatever time is decided upon, is that eating is initially a pleasurable experience and should continue to be so. The more anxious parents are to "make sure the baby eats well," the more likely are they to make the child uncomfortable about eating. Most infants begin by sucking small amounts of food from the end of the strange, unfamiliar spoon, and the sucking movements sometimes result in pushing the food out instead of back. But if they are not hurried or urged, they continue in their natural eagerness to be fed.

At one year, more or less, self-feeding begins. Sometimes a baby indicates his readiness for this by wanting a spoon of his own, and sometimes by using his most natural instruments, his fingers. He is encouraged at this notoriously "messy" phase if meat, vegetables, and fruits are furnished in small pieces easy to pick up. His "emotional nourishment" continues if he is not nagged or pressed to be neat and careful, which he is not yet able to be. It is far more sensible if his dishes, for instance, are plastic, his bibs easily laundered (old cloths or diapers), and his eating area protected by a piece of linoleum. "Emotional starvation" in the form of disapproval of the way he eats or of his rejection of some foods, can substantially affect his appetite. Studies of babies have disclosed that, left to their own choice of nourishing foods over a period of time, they select for themselves a well-balanced diet in the long run.

Sleeping.—As they differ in feeding schedule and in appetite, infants also differ in their needs for sleep. Most newborn babies are awake only for feedings, about 2 or 3 hours out of 24. By the time a child is half a year old, this usually changes to about 12 hours of sleep at night and several hours during the day. The daytime sleep may be a few short naps or a short one and a long one. Here again, reasonable self-demand can prevail. There is no harm, for example, if a baby seems to have his wakeful periods at night—when parents need their rest—in deliberately keeping him awake for longer spells during the day or toward evening. Sound sleep is important to his health and happiness, however, and he should not be awakened, for instance, to be shown to eager relatives. In general, by the time an infant has fallen into a regular eating pattern, his sleep pattern also becomes fairly regular. Of great importance for good sleeping conditions is a firm, flat mattress. The flat, unsagging surface is necessary for good posture development and also enables the baby to turn his head easily from side to side.

Bathing.—Every aspect of a child's care enters into his need for satisfactory relationships with others. One contribution to his sense of trust is being bathed by assured, unhurried hands. A bath is fundamentally a pleasant experience for an infant—he is free of clothing, able to move without inhibition, and happy with the sensation of the water.

Since most doctors believe the navel should be kept dry until it is completely healed, daily baths do not usually begin until that has occurred. Subsequently, there need be no rigidity about its being daily. If the house is chilly or the parents tired, it is much better to skip the bath than to expose the baby to chill or to a hasty, tense experience. Having a specific area set aside for the bath, with

all necessary materials and clothing handy, makes it even more enjoyable for the adult and less of a chore. Being placed too swiftly in the water, finding it too hot or cold, feeling that the hand grasping him is unsteady, can arouse fear in the infant and make him unhappy not only with his bath, but also in some cases with later attempts at swimming. Nose, eyes, and mouth need never be cleaned. "Cradle cap," the greasy crust that may appear on the head, can be removed by rubbing in petroleum jelly at night and washing the head thoroughly for several days.

Toilet Training.—Many indications of ill effects from too early or too rigid toilet training raised the practical questions: "When?" and "How?" It is generally agreed that toilet training should not be undertaken in infancy or the first year of life, for most babies are not ready to start learning bowel control before about a year and a half. Only by that time have they developed sufficiently to associate the physical feeling of need to empty waste with a special place for doing it. Hurrying the process may, for one thing, serve to delay it in the long run and, for another, injure the trusting relationship between parent and child. Feeling himself urged to do something he cannot do, and then feeling disapproval, an infant can come to see the pressuring adult no longer as a friend. Even if, out of fearing the disapproval and desiring to please, he does achieve control of a sort, it is not true learning and there is a chance of his reverting to lack of control later in childhood. In addition, it has been shown that children can come to associate the fear and disapproval with their excretory and genital organs.

In judging a baby's readiness for toilet training, it is well to consider whether or not he seems to know what the toilet is for (from having seen the rest of the family use it); whether he gives some signal (grunting, getting red in the face, or straining) just before a bowel movement; whether the movements come at fairly regular intervals; and whether he is willing to sit on the toilet.

Immunization.—Since the time of Louis Pasteur (1822-1895), medical science has provided us with many special techniques for preventing communicable diseases. Standard practice in child care today includes the immunization of children against specific diseases. The oldest kind of immunization in general use is of course smallpox vaccination. The most widely used procedure is to immunize children during the first year against diphtheria, whooping cough, and tetanus with a compound injection that protects against all three diseases. Later the child is vaccinated against smallpox. Some of these immunizations are effective for many years; some have to be reinforced from time to time.

Saving Babies' Lives.—The best indication we have today of the value of the various measures that research workers have developed for improving the health of our population is the striking reduction in the infant death rate since the beginning of this century. The first year of life is the most precarious: during that year more individuals die than at any other age. At the beginning of the century, more than 13 per cent of the babies born alive (135.3 per thousand) died before the end of their first year. In 1954 this rate had dropped to about 27 per 1,000. The factors involved in this great improvement included not merely the medical advances but better homes

and living conditions, better sanitation, better nutrition, better maternal care, better working conditions, and a healthier outlook upon life. A significant feature of the total reduction in the infant death rate is the great variation among different regions and among different sections of the population. In 1949, for example, the infant death rate varied among the different states from less than 24 to more than 60 per 1,000. There are, however, many indications that, with our present technical and economic resources, close to 99 per cent of all babies could be safely carried past their first year.

Creeping and Walking.—Most infants begin to creep or crawl at about eight or nine months and, given the space, move forward not only physically but, intellectually, emotionally, and socially. It is at this time that parents find it best for all concerned to remove perishable or dangerous objects from low shelves and tables; to encourage the creeper to come to them from across the room; and to furnish balls or other rolling toys that he can scuttle after. Playpens are valuable when there is no adult available to watch over the infant, but he should have as much roaming space as is convenient for the family.

At a little less than a year, infants in general begin to pull themselves up to standing position and some take to climbing. Some mothers and fathers sense in themselves, at this phase of their child's growth, the anxiety commonly called "overprotectiveness." The infant needs to climb, but the adults sometimes have undue fear that he will hurt himself. If he is permitted to clamber about under a watchful eye, they usually find that much of their protective impulse is unwarranted. While an infant cannot be permitted to get himself into situations that older people know from experience to be dangerous, he can for the most part take the ordinary bumps inevitable in learning to get about on his own.

There is great variation in the ages at which walking begins, but most babies seem to take their first shaky steps somewhere around a year. They are helped most when adults encourage by voice, praising the attempts, but are not helped when pulled up or held too much by the hands. Walking alone, commonly occurring between 12 and 15 months, opens still wider the fields for the infant's growing curiosity, his desires to expand socially and intellectually. He wants to explore and discover with his body, mind, and feelings.

Talking.—At about a year, infants in general say a word or two with some sense of what they are saying. Before this time, they "speak" in their own way in imitation of adult speech sounds. When they do begin to use specific words, they need even more examples of clear, understandable language in the grownups around them. If their own first babyish attempts are repeated to them, whether teasingly, lovingly, or correctively, as "baby talk," they are likely to repeat these sounds, since they are still imitating. Often, babies who talk a bit before walking will slow down in learning new words while they are learning to walk.

Play.—Playing with a baby comes so naturally to adults, is such a spontaneous part of being with him, that they seldom consider that it can be more than fun. But play is a vital factor in the child's all-round growth. First, the fun of course makes him feel it is good to be with people. He is on the road to understanding others and becoming a social being. The infant who lies lonely in his crib most of the time, attended only when he is wet or hungry, is not likely to start

out on a basis of liking, trusting, and knowing others. Furthermore, play helps the baby develop physically. Aside from play with people, the toys he is given to play with by himself can encourage his skeletal and muscular development. A bright object or "gym" set up over his crib, for example, supplies incentive for stretching and grasping. When he begins to creep, balls or other toys that can be pushed away and then scuttled after help his developing leg muscles. Toys also help satisfy his expanding sensory and intellectual needs. Rattles to shake and listen to, bright pictures to look at, and kitchen utensils to bang, take apart, and try to put together, offer him learning opportunities. Mothers and fathers can often see for themselves what type of plaything their infant is ready for simply by observing what sounds, sights, and objects around him seem to please him most.

Common Problems in Infancy.—It is clear to most of today's parents that the one-time eating and sleeping problems are not innate. Infants have a need to eat and sleep, and barring the effects of illness or physical disorder, problems arising in this connection are created. There are, however, numerous types of behavior that are still called problems because they worry parents. Some of them appear purely physical, some emotional. As has been pointed out, they are usually interwoven. An infant whose parents are so concerned about inhibiting his emotional growth if they should say, "No," that they allow him to eat city sand pile dirt is exposed to disease. On the other hand, the one whose mother and father are so concerned about germs that his clothes are constantly being changed, his hands and face constantly dabbed at, loving relatives kept at a distance, is equally exposed in such a sterile environment to emotional disease. Some of the problems are not directly connected with the infant himself but arise from false concept or rumor. A few of these worries most common to parents are:

Colic.—Symptoms of the intestinal cramps known as colic, usually limited to the first three or four months, are violent crying after feeding, drawing up of the arms and legs in pain, and reddening of the face. The precise cause is not agreed upon. But things to consider in trying to help the baby are: whether he is subjected to too much excitement, whether some food may be the cause, whether he swallows too much air in feeding, and whether his overall environment is a relaxed, easygoing one.

Teething.—At one time, all sorts of sickness were attributed to teething, but in itself it cannot really cause illness. A baby may be fretful and cranky or not eat so well as usual when a tooth is coming in, but if he becomes sick at the time it is not directly because of teething. Having things to bite on, such as hard rubber or plastic rings, will relieve both pain and the urge to bite. There is considerable variation among children as to the times that teeth appear, but on the average infants cut their first two lower middle teeth at about six to eight months and four upper front teeth after a few more months have passed. The set of "baby" teeth is usually complete at about the time the child celebrates his second birthday.

Crib-rocking and head-banging.—Some kind of inner urge, perhaps a need for rhythmic movement or for letting off excess energy, impels many infants to rock themselves so violently that their cribs rock too. In some cases, they bang their heads against its sides. Padding keeps them from hurting themselves, and lack of anxiety about the

matter in the parents keeps from building up a tense atmosphere that may itself contribute to this rocking and banging. If the activity is persistent and parents cannot help but worry, a talk with the baby's doctor may bring some helpful answers to light.

Thumbsucking.—Infants are born with a strong need to suck. In the beginning it is their only way of getting food. Since it is such a source of pleasure and satisfaction, most of them don't seem to get enough of it and take to sucking thumbs or fingers or other objects. Stopping them with "no" or with mechanical devices or more subtle forms of disapproval is very likely to occasion unhappiness, bewilderment, and possibly resentment. Providing pacifiers in some form is more sensible if the use of thumb or fingers is worrisome to the parents. Sometimes excessive sucking is a sign that the infant is removed from the breast too soon, or that the holes in rubber nipples are too large to give him sucking satisfaction. It can also be a sign that he needs more in the way of affectionate attention.

Smothering.—Old wives' tales and news headlines notwithstanding, actual smothering is not a danger for the sleeping baby, as so many parents fear. Infant deaths attributed to smothering are usually caused by some sudden illness. It is a temptation to mothers and fathers to take their baby into bed with them occasionally, but tragic reports of accidental smothering when the parents fall asleep make it a temptation to be resisted. If a baby is lying on a firm, flat surface without a pillow, and with the blankets, sheets, and other bed covers securely tucked under the mattress or pinned down at the corners, there is no danger of a healthy child suffocating.

Spitting up.—Many infants spit up a bit after feeding, in most cases, apparently, because they are too full. It is not generally a sign that anything is wrong. If the amounts spat up are large, or an infant does it all the time, the matter should be called to the doctor's attention.

Hiccups.—Infants frequently have hiccups, especially after a feeding. Ordinarily the hiccups do not last long and are not harmful. Burping the baby, rubbing his abdomen, or giving him a sip or two of warm water will usually dispel them.

Fontanels.—The two soft spots on the infant's head, where the bones have not yet grown together, are actually covered by a strong membrane, and parents need have no fear of washing the infant's scalp thoroughly.

Crying.—All babies cry more or less, since crying is their only means of responding to needs, pain, or discomfort. Hunger, discomfort from wetness or chafing or heat or cold, fatigue, over-excitement, or plain bored loneliness are among the many possible causes. Often, when a checkup fails to reveal any specific cause for crying, and being held and cuddled do not bring relief, parents may discover, by just letting their infant cry for a while, that the wails last only a few minutes and that he then settles down happily.

Breath-holding.—Occasionally, an infant may hold his breath to a point where it seems he will suffocate himself. It has been definitely found that he will not. Breathing is automatic, for a certain imbalance of oxygen and carbon dioxide forces the movements of breathing. If little attention is paid to the breath-holding, or if something interesting is offered to divert the infant's attention, it will pass.

Fears.—It is not uncommon to find parents

worried over the fact that their baby of a few months seems afraid of things that didn't disturb him at all when he was younger. Since there are actually many things in the world that may reasonably be feared until they are understood, such displays of fearfulness are very often a sign of the baby's sensory and intellectual growth. For example, at eight months or so many children suddenly begin to cling to parents who are going out. They have learned that things and people can go away. Handled sympathetically, not shamed or punished, they soon progress to the certainty that these things and people also come back. Of course, outer circumstances can create fears in babies. The noise of a vacuum cleaner, slipping in the bath, being violently seized if he tries to pat a dog, thunder and lightning, and darkness are the sorts of thing that may make a baby inwardly fearful. In such cases, the infant most needs gentle reassurance and the feeling of adult arms around him.

Heredity, Environment, and the Individual.

—The question, "Which is more important, heredity or environment?" is a poor one. The constructive view is simply a recognition of both as inseparable from life and from each other. An individual of a given inheritance is influenced by a given environment in one way; a different individual responds to the same environment differently. Side-by-side with the many studies and conclusions about the *average* infant has grown the recognition of the *individual* infant. Authorities speak of an infant needing *about* so much food, *about* so much sleep, and of walking and talking at *about* a certain age—for the average is put together from the very individuality of thousands of infants. Hereditary physical differences are obvious to most people. What is not generally kept in mind is that personality differences too are observable in the first few weeks of life. Within the same environments, for instance, some babies seem to have "just been born" slow-paced and calm, and others seem to have been born energetic, sensitive squirmers. Some suck heartily and avidly, others slowly.

Although the modern parental attitude toward the importance of environment and the knowledge of phases and growth and development constitutes an immense step toward bringing up healthy and happy children, always the keynote of this attitude must be respect for the infant's uniqueness and his right to be different. Inwardly, the infant has his own pattern and potentiality for development. Outwardly, his needs from adults are affection, guidance, and encouragement. INFANT, in law, a person who has not reached the age of majority, which is usually 21 years. At common law, majority is reached on the day before the twenty-first birthday, but it may be attained at an earlier age if the applicable statutes so provide. The status of infancy is attended by numerous legal consequences, in-

cluding provision for care and custody of the infant by the state when necessary, special protection against certain criminal acts, some degree of mitigation of criminal liability, and the application of special rules relating to property transactions and contracts. An infant who is not subject to parental control and custody becomes a ward of the state, which may exercise its guardianship by providing reasonable regulations for the minor's protection. Usually the state provides special courts, charged by statute with the care, control, and custody of neglected children. These juvenile courts also have jurisdiction over delinquent minors, for the primary purpose of rehabilitating them rather than punishing them with the same severity as would be appropriate in the case of adult criminals. At common law, however, children can generally be held liable for crime the same as adults; and it is only by statute that the prosecution and punishment of infants are made subject to substantially different rules than those applicable to adult offenders. The common law allowed complete exculpation from criminal liability only to infants under seven. In legal terminology, such children were said to be conclusively presumed to have no capacity to commit a crime. Between the ages of 7 and 14 there was a presumption of incapacity to commit crimes, which decreased in strength as the child grew older. After 14, an infant was presumed at common law to be completely capable of crime and was accordingly subject to penalties as severe as those inflicted on adults.

In the fields of property and contract law, infants are subject to special rules, which are called disabilities, but which are actually favorable to their interests. The underlying purpose of such rules of law is to preserve the infant's property intact until he reaches majority. An infant may own property and may acquire property rights, but is not permitted to have control and custody of his property and is severely limited in the disposition that he may make of it. An infant's purchase or sale of property is voidable, which means that it can be set aside, or "avoided," if he so chooses after he comes of age. The same general rule applies to most contracts entered into by infants, with the result that the other party to the contract cannot be sure what his own legal rights and liabilities are until after the infant has reached majority. The avoidance of a purchase or contract (also sometimes called disaffirmance) must take place within a reasonable time after the infant attains adult status. Any act on the part of the infant which clearly shows an intent not to be bound by the transaction is sufficient to constitute an avoidance. Examples of such acts are suing to recover the purchase price, interposing infancy as a defense to a suit by the seller for the price, and restoration of the property to the seller. The opposite of avoidance is ratification, an act by a person after reaching majority which indicates an intention on his part that a transaction entered into during his infancy shall be binding upon him as well as upon the other party. Ratification may be accomplished by an express promise to fulfill the terms of an agreement previously made, by performance of such agreement, by retaining or accepting the consideration for a transaction entered into during minority, or by other conduct demonstrating an election by the erstwhile infant not to avoid the contract in question. The general rules limiting an infant's power to make binding contracts are not applicable

to agreements authorized by statute (such as marriage) and agreements for necessities, including food, clothing, shelter, medical services, and education.

RICHARD L. HIRSHBERG.

INFANTE, in-făn'tă, the name borne by any legitimate son of a king of Portugal or Spain, with the exception of the eldest. The heir to the Spanish crown was called *El Príncipe de las Asturias*. *Infanta* was the name borne by a daughter of a king of Portugal or Spain and by the wife of a king's son.

INFANTICIDE, in-făn'ti-sid, the murder of a child born alive, as distinguished from abortion, which is the destruction of the fetus in the womb. In primitive societies the origin and the aims of infanticide are generally impossible to discover, but are often related to the existing food supply as well as to various religious and social taboos. In civilized societies the causes of infanticide include the facts that a child is unwanted and that the shame induced by a dread of the social disgrace attaches to mothers of illegitimate children. The sanctity of human life, from its beginning to its close, is a maxim of modern civilization, except during "total" war and in certain dictator-governed or Communist-controlled countries, and the law treats as a murderer whoever performs infanticide.

INFANTILE PARALYSIS. See POLIO-MYELITIS.

INFANTRY, in-făn-trī, that branch of an army which is trained, equipped, and organized to fight on foot. Modern infantry may be transported to the battle area by aircraft, ship, train, trucks, or armored personnel carriers, but it normally assaults enemy positions or defends against an enemy attack on foot. Infantry forms the backbone of any army and comprises the bulk of the combat arms. It is the arm of close combat in that it physically engages the enemy. In offensive warfare it has the task of closing with the enemy and destroying or capturing him. In the defense it denies selected localities to the enemy and destroys him by counterattack.

Arms.—Infantry can fight on any terrain and is more independent of weather conditions than any other service or arm. Through the centuries, infantry was armed with sword, pike, and musket. Modern infantry is armed with rifles, bayonets, automatic rifles, machine guns, mortars, grenades, antitank weapons, recoilless rifles, flame throwers, explosive charges, tanks, and assault guns. Prior to World War I, the majority of the firepower of infantry was furnished by the rifle. This proved far from sufficient, and with every year of the war new weapons were added to the infantry units. In modern infantry divisions only about one third of the soldiers are riflemen.

Support.—Infantry by itself is capable of only limited independent action utilizing its own weapons. For decisive action it must be adequately supported by artillery, combat aviation, missiles and rockets, engineers, and tanks. Thus, infantry rarely fights alone. For the most part, it participates as part of combined arms teams, such as the infantry-tank team and the infantry-artillery team.

Organization.—Combat troops of all fighting arms are organized, with service troops, into in-

fantry divisions. Each division is commanded by a major general. The supporting arms and services assist the infantry in the accomplishment of its mission. Infantry divisions in most armies consist of three regiments, or brigades, of three battalions each. The regiment is commanded by a colonel, while a lieutenant colonel commands a battalion. Each battalion consists of three rifle companies, commanded by majors or captains. Each company consists of three platoons, commanded by lieutenants. The triangular nature of the organization is completed with each platoon being composed of three rifle sections or squads under the command of sergeants and corporals. The United States Army departed drastically from the triangular concept in 1957. It reorganized its infantry division into five battle groups. (See section on *United States Reorganization*.)

HISTORICAL DEVELOPMENT

Early Infantry.—The history of warfare is largely the history of the infantry. Except for a relatively short period in the Middle Ages when the mounted warrior was supreme, the infantry has been the basic arm, the winning of wars being determined by the actions of the infantry.

At the dawning of civilization man first fought as an infantryman. He resorted to stones and clubs and defended himself by building huts and surrounding them with stakes. Early organization consisted chiefly of loose groupings of individuals. Organization for war has been changed through the centuries by the development of new weapons. Similarly, tactics are dependent upon the weapons with which the infantry wages its battles. Thus, bronze and iron weapons replaced clubs. The result—new organizations and new tactics.

The earliest known national infantry was the Egyptian light infantry. Some of its members carried swords, while others were archers and slingers. Soldiers of the Egyptian heavy infantry carried large wooden shields for protection and were armed with spears six feet long.

Greek.—The Greeks amassed their power and accumulated their wealth by war, and the Greek armies consisted almost entirely of infantry. In battle the Greeks after the mid-4th century B.C. relied upon an infantry unit called the phalanx, a large group of infantry closely grouped together in a box formation and armed with a deadly spear, some 21 feet long. The first five ranks held their spears in horizontal position as the entire phalanx advanced and engaged the enemy. This formation offered little opportunity for maneuver, but was successful because of the tremendous shock effect that it had on the enemy.

Roman.—With the passing of the Greeks, the Roman Army, an infantry army, became supreme. The basic unit was the flexible legion, which consisted primarily of infantry. The legionary infantry was armed with shields, body armor, and a short heavy spear or javelin; however, the primary weapon was a double-edged sword, 20 inches long, that was used for thrusting. In Gaius Julius Caesar's (100?-44 B.C.) battles, the legion moved into the attack at a walk, in lines 8 or 10 feet deep. When it reached within 100 yards of the enemy, it took up the charge. Javelins were thrown at 15 yards, and then the Roman infantry assaulted with their deadly swords. The men in the rear continued to throw javelins at the enemy and moved in with the sword only to replace friendly casualties. The resultant havoc created by the Roman sword caused the aftermath of the

battlefield to be called the goriest sight in all history. The Roman infantry was supreme because of discipline, promptness in making required improvements, and care in selection, training, and exercise of the individual soldier. Discipline was lost under a succession of weak and profligate emperors. The legions deteriorated to such an extent that the Gothic cavalry from the East slaughtered the Romans at Adrianople (Thrace) in 378 A.D. After this battle, cavalry dominated warfare and the infantry declined into impotency. Adrianople heralded the end of the Western Roman Empire and the onset of the Dark Ages.

Medieval Infantry.—The Swiss pikeman and the English longbow man restored the infantry as the basic arm of battle and relegated cavalry to a supporting role. The Swiss infantry was the finest in Europe for centuries, because of its drill and equipment, and the fighting character of the soldiers. Swiss infantry victories in the 14th and 15th centuries showed that the day of the mounted knight was waning. The English annihilated a numerically superior mounted French army at Crécy (France) in 1346 by using the longbow, a bow six feet in length, capable of delivering two shots a minute with great accuracy at a range of 200 yards. French cavalry were slaughtered by the longbow much as were the Burgundian cavalry who attacked the massed pikes of the Swiss infantry at Grandson and Morat (Switzerland) in 1476 and at Nancy (France) in 1477.

Firearms.—The doom of mounted knights was sealed forever with the advent of firearms. Infantry regained the universal esteem and importance that it enjoyed in ancient armies and that it enjoys today. Early firearms were handguns consisting of barrels lashed to a stick and fired by a match. The Swiss at Morat (June 22, 1476) had over 6,000 handgun men to support their pikes. The next development was the matchlock harquebus, the forerunner of the musket. In 1540 a small harquebus two feet long with a curved handle was developed. It was called the pistol. In 1570 the musket began to replace the harquebus. It was provided with a matchlock that fired the charge by bringing a match in contact with gunpowder in the pan. The musket was so heavy that a forked rest was required to support it.

Early Modern Period.—Gustavus II (Gustavus Adolphus) of Sweden (r. 1611-1632) developed modern infantry organization and tactics. He borrowed from Maurice of Nassau, Stadtholder of the Dutch Republic (1587-1625), and from the Dutch.

Swedish Infantry.—Gustavus' battalions consisted of 4 companies, each with 54 pikemen and 72 musketeers. Swedish infantry attacked in six ranks that were divided into two firing lines, three files deep. Each musketeer hastened back to the rear to reload after firing, thus maintaining a continuous fire. The three-deep firing line of Gustavus survived two centuries, until the breech-loading rifle caused it to be replaced.

Firearms.—During the 17th century the firelock gradually replaced the matchlock as the infantry weapon. A charge of infantry no longer meant a collision of forces with pikes engaged. It meant instead a fire fight at close quarters until one side retreated. Pikemen were gradually abandoned because little use was found for them. The bayonet was devised to replace the pike. It was designed initially to assist infantry in fighting cavalry. Another development produced grenades, which were used to considerable success by infan-

try during the sieges of the Thirty Years' War (1618-1648).

Prussian Infantry.—The pattern of excellence for infantry was next established by Frederick II the Great of Prussia (r. 1740-1786). He planned his battles as a series of complicated maneuvers which required constant practice. He discouraged open fighting and had mechanical precision as his aim. This precision was of great importance in rapid loading and firing. Frederick's tactics were much copied, but rarely with the same success. Those who copied did not realize that it was the precision created by repetitious drill, and not the tactics per se, that led to Prussian victories. Frederick closed the era of linear tactics. This was proved when Maj. Gen. Edward Braddock, emulating Prussian drill procedures and following the Marlborough (John Churchill, 1st duke of Marlborough) type of fighting, was soundly defeated on the Monongahela River near Pittsburgh, Pa., in 1755 by the French and Indians, who employed mobile and flexible infantry tactics.

American Colonial Infantry.—American colonists adopted the tactics of the Indians by organizing units of light infantry or rangers. A compromise, which was between the rigidity of Braddock and the fluidity of the Indian, was subsequently adopted. During the War for Independence (1775-1783) the Americans took advantage of the available concealment and, utilizing flexible tactics, defeated some of the best regiments that Europe could muster. The precise Frederickian drill and formations had little effect against such tactics. This open-type fighting experienced by the British during the American Revolution created a profound effect upon Napoleon I (r. 1804-1815).

French Infantry.—French troops under Napoleon made use of small columns of infantry for maneuver and assault and of deployed lines for firing. Napoleon achieved great success against massed formations, employing such tactics in his earlier battles. But as the years of war continued and the caliber of the French infantry was reduced by the costly attrition, he resorted to greater use of masses instead of the light speedy open-order lines of earlier days. Napoleon's infantry was armed with the musket and bayonet. This latter weapon was given added emphasis, because Napoleon was a great believer in using the bayonet for the final charge of the French infantry.

American Civil War.—The Civil War (1861-1865) developed a system of advancing by rushes, with half of the men rushing and lying down to avoid losses and the other half firing to reduce the enemy fire. The difficulties inherent to this means of infantry advancing were that the men had to stand to load their muzzle-loading weapons, and it was difficult to make men advance once they were in the prone position. The actions were almost always decided by infantry fire. Bayonets were rarely used. The war showed the importance of looser fighting formations, the necessity of advancing by rushes, and the need for increased use of entrenching tools.

World War I.—Early in World War I (1914-1918) advances were made by infantry in lines of skirmishers or by staggered platoon columns. The deadly effect of the machine gun forced the interval between infantrymen to be increased from one to five paces. This made control of the men by the squad leader difficult.

Tactics.—The old system of advancing by

rushes was abandoned, because it was almost impossible to make men rise from the prone position and advance in the face of machine-gun fire. The machine gun produced a more deadly fire than could an entire company equipped only with rifles. A line of skirmishers offered the ideal target to the machine gunner. To counteract the effect of the machine gun and to reduce the exorbitant casualties which occurred in the initial stages of the war, new tactics had to be developed. The result was a reliance on tremendous artillery concentrations, the use of smoke to hinder enemy observation, and the employment of infiltration tactics. The infantry altered its procedures and abandoned attacking in long lines, shoulder to shoulder. Instead, it attacked by squads and platoons, utilizing the ground for all possible cover and protection. Each unit moved forward regardless of the progress made by units on the flanks. Enemy points of resistance were bypassed. The uneven progress of attacking infantry allowed men of supporting units, who were advancing behind leading elements of an unchecked unit, to fire into the flanks of the bypassed enemy. Tactics thus consisted of infantry units moving forward, first one unit and then another, wherever the enemy's resistance proved weakest. Reserves were committed to exploit success and not to reinforce or to redeem failure. Gains made were thus exploited by dispatching reserves through the points of breakthrough.

Support.—World War I was a static war of trench warfare with complicated networks of barbed-wire entanglements. The infantry had to rely on supporting arms to a degree never before experienced. The success of the defender's machine guns led to the development of the tank by the British. The slow-moving early tanks were capable of moving against enemy machine guns. They were used with success despite the numerous mechanical breakdowns that occurred. Mortars and small howitzers became organic to infantry units for close support. Dependence on strong artillery support for survival on the battlefield became mandatory. Infantry divisions were organized during the war to meet the exigencies of trench warfare. Half of the infantry of each division held the line, while the other half rested; thus, the infantry division consisted of two brigades, each having two regiments.

World War II and Korea.—The period between the world wars was one of improvement in the means of transportation both in the air and on the ground. Tanks and aircraft played a prominent role in the minds of military planners, with the result that armored (tank) and mechanized divisions were formed early in World War II (1939-1945). The infantry of World War II was also a modern force capable of performing at rapid speeds, being dropped by parachute, or landing in special amphibious craft on well-defended shores. All armies of World War II contained large amounts of infantry. The Russian and the German armies each had several hundred divisions, while the British, Japanese, and Chinese armies had somewhat less. The United States Army had 78 infantry divisions, 5 airborne divisions, and 16 armored divisions. In addition there were 6 Marine divisions, essentially infantry divisions, but specially trained for amphibious warfare.

Mobility.—The infantry fighting in World War II and in Korea (1950-1953) was similar to that of World War I, but differed in the mobility of the infantry. The foot soldier had organic ve-

hicles which transported him to the battlefield. Forced marches, long a characteristic of trained infantry, were rarely utilized. Infantry units were not limited to movement by foot, except as a last resort, when, because of difficult terrain or lack of transport vehicles, there was no other way to move. The force with inferior mobility was the defeated force. The bypassed Japanese infantry in the Pacific fought with a determination and tenacity rarely seen. But with the cutting of their supply lines they were reduced to immobility and had to remain in static positions. This resulted in inevitable defeat.

Tactics.—During World War II and in Korea, infantry companies attacked in a manner similar to the so-called infiltration tactics used in World War I. In the triangular organization, a company commander usually attacks with two platoons in the assault echelon, keeping one platoon in reserve for commitment at a decisive place. Under the cover of artillery and mortar fire (which sometimes included the support of combat aviation and naval gunfire), the attacking platoons moved either in column or in a line of skirmishers with five paces between soldiers. Troops approached the enemy position rapidly, making the maximum use of covered and concealed routes, supporting fires, and smoke screens. A platoon not stopped by enemy fire pushed on regardless of the progress of adjacent units. When enemy fire was received, the infantry "hit" the ground and returned the fire, trying to gain fire superiority. When such superiority had been gained, the infantry continued to move forward by a combination of fire and maneuver. If superiority could not be gained, the company commander would commit the reserve platoon to approach the enemy from a new direction. Infantry attempted to get as close to the enemy as possible before the artillery and mortar fires were shifted because of the danger to the attackers. This shifting of friendly fires frequently occurred within 75 yards of the objective. In this position the troops were organized into a skirmish line, if they had not previously adopted such a formation, and moved the short remaining distance, rapidly delivering a heavy volume of rifle fire while moving. This assault was frequently conducted at a walk rather than at a run, because a network of enemy positions in depth had to be reduced by grenades, flame throwers, and explosive charges. In the early stages of the war, infantry-tank teamwork was poorly coordinated, but after improved training the attacking infantry normally assaulted an enemy position with the assistance of tanks. This made the infantry task much easier. Another development was the use of the flame-throwing tank. This weapon could spurt bursts of flame from 100 to 200 yards, eliminating the enemy or demoralizing him so much that little resistance was encountered. Current infantry assault tactics for most armies include increased reliance on supporting fires, the use of infantry-tank teams, and, in particular, the use of flame-throwing tanks to support the infantry in special operations.

Casualties.—World War II and Korea exacted high demands from the infantryman. The battles were really fought in the rifle platoons. In these platoons there were the heaviest casualties, because the riflemen engaged the enemy in close combat. It was on the members of the rifle platoons that the onus of war fell—they had the least statistical chance for survival. There was rarely shelter, beds, or safety for the rifleman. He slept

in a trench or a foxhole often filled with water. He fought without promise of either reward or relief. He fought because of the discipline that was instilled in him, pride, belief in cause, and because he did not want to "let down" his fellow infantrymen.

Behind each rifleman in the United States Army in Europe during World War II were 15 other soldiers supporting him. The infantry comprised less than 20 per cent of the ground and air forces of the United States in World War II, yet it sustained 70 per cent of the casualties. It sustained 90 per cent of the casualties among the United States ground forces. Figures for infantry of other armies were comparable.

Morale.—Because of these conditions, all armies adopted campaigns to publicize and to glorify the foot soldier. At the start of the war the newer fighting forces—the air forces and the tank units—received the plaudits of the press, with the result that few men desired to be in the infantry. As the war progressed, the role of the infantry was given the publicity which it merited. The civilian populace finally realized the importance of the infantry and the courage required of an infantryman. In the Russian Army, political commissars extolled the role of the infantry to the soldiers and indoctrinated them with the importance of their fighting. The United States Army adopted a special badge of merit and gave special pay to combat infantrymen to reward those who bore the brunt of the fighting. Recognition of the importance of his job aided the infantryman immeasurably in the performance of his arduous duty.

MODERN ORGANIZATION

Armored Infantry.—Armored infantry is that form of infantry that is part of an armored (tank) division. The technical improvements in the tank's mobility and firepower in the years following World War I introduced the concept of armored tactics and the organization of armored or tank divisions capable of great mobility and of rapid exploitation. Initial German tank divisions in World War II contained no accompanying infantry. This was found to be a serious limitation, because tanks alone had difficulty in reducing enemy positions prepared with antitank guns, mines, obstacles, and other barriers. Therefore, mechanized infantry that could move at the same speed as the tanks was added to the armored division. Personnel carriers that gave the infantry some degree of protection were subsequently developed. The initial ratio was three tank units for every infantry unit. This proportion was found to be wanting in infantry. It was later changed to two to one, and finally to one for one. Armored divisions now contain equal amounts of tank and infantry units. (The United States division contains four tank battalions and four armored infantry or rifle battalions.)

Mobility.—Armored infantry is completely mobile. Each squad has its own armored personnel carrier, a fully enclosed, full-tracked, armored vehicle giving protection from small arms fire and shell fragments. Armored infantry usually assaults enemy positions dismounted, but it is accompanied or supported by tanks.

Flexibility.—Flexibility of organization is the most important aspect in the employment of armored units. This makes them capable of being readily adaptable to ever-changing battlefield conditions. Armored infantry rifle companies operate

either as a part of their own battalion or attached to a tank battalion. Similarly, rifle platoons operate with their own company or attached to a tank company. Thus, infantry and tanks are normally formed into combined arms teams at the platoon, company, and battalion level. Depending on the mission, some teams are tank heavy and some are infantry heavy. Infantry-weighted teams are used to attack in cities, against prepared positions, in dense woods, and in other areas not conducive to rapid movement by tank-weighted forces.

Airborne Infantry.—A new tactical development during World War II that resulted from mechanically sound aircraft was the vertical envelopment. Infantry was transported to the combat zone by parachute, gliders, and assault transport aircraft.

The Russians were the first to mass-train paratroopers. As early as 1935 the Soviet Army had one trained parachute infantry battalion. The Germans quickly organized parachute units and used them with limited success in the attack on Norway in 1940. The German airborne assault on Crete in 1941 was more successful. A parachute battalion captured key airfields on which troop carriers subsequently landed. Gliders were also used at Crete, but these craft suffered such severe damage in landing that the Germans did not use them again in an assault role.

Great Britain and the United States also developed airborne units. The British organized two divisions in late 1941. Each consisted of one glider brigade and two parachute brigades. The United States ultimately organized five such divisions. The largest operation was the attack of the first Allied Airborne Army into the Netherlands in 1944. The air armada carrying this force of over three divisions consisted of nearly 1,500 transports and 500 troop-carrying gliders.

Tactics.—Early airborne operations in World War II amounted to little more than surprise raids by parachutists. The infantry in the drop zone was vulnerable to enemy counterattacks, particularly by tank forces. It was found necessary to supply the initial lightly armed forces with heavier weapons and to develop a battle plan enabling them to link up quickly with friendly ground forces. The tactics developed for the airborne infantry involved landing behind well-entrenched defenders, cutting supply lines, disrupting reserves, and forcing enemy pressure away from other friendly units. The usual operation was called a link-up. It involved a landing behind enemy lines and an early juncture with friendly surface forces. The initial objective of parachute infantry was to secure landing sites, where gliders and aircraft could land heavy weapons and equipment in the airhead. This gave the airborne force a better chance to defend itself against counterattacks until the link-up with friendly forces was effected. Once landed, however, the airborne infantry fought as conventional infantry. In fact, the only difference between airborne or armored infantry and any other infantry is the means used to get it on the battlefield.

Transport.—Gliders fell into oblivion because they were easily damaged, immobile on the ground, and difficult to navigate. In addition, their load capacity was limited. They were replaced by newer types of aircraft that were capable of landing in relatively small areas.

All modern infantry can be transported by air. The airborne division differs from the regular infantry division in that it can be landed by para-

chute. Training in air loading and air landing is a prerequisite of all infantry.

The development of the helicopter has caused added emphasis to be given to the vertical envelopment tactical concept. The difficulty in parachute operations was the relatively long training period required, dispersion in the drop zone, lack of heavy equipment to combat enemy counterattacks, and lack of secrecy. Air movement by helicopter requires little or no extra training on the part of troops; it is exact, as far as landing in the desired area is concerned; and it facilitates evacuation, if necessary. However, helicopters are vulnerable to enemy fire and are limited in range. Consequently, future operations involving airborne infantry will still require some movement of troops by parachute. But this movement will be less than experienced in World War II.

Soviet Infantry.—Divisional Types.—There are three basic types of divisions in the Soviet Army: tank, mechanized, and rifle. Of the estimated 175 line divisions, 110 are rifle (infantry) divisions (in the mid-1950's). The rifle divisions have motorized equipment, organic tanks, and artillery. Since World War II, considerable attention has been given to modernizing the equipment and the weapons of the Soviet infantry.

Organization.—Soviet organization of infantry closely paralleled that of the United States Army before 1957. The Soviet rifle division is organized on the triangular concept. It consists of 3 rifle regiments with about 2,500 men each, supported by an artillery brigade and a tank regiment. The tank division has relatively little infantry. It contains one mechanized infantry regiment and three tank regiments. The mechanized division is built around three mechanized infantry regiments, two tank regiments, and supporting artillery.

In the rifle regiments, there are three rifle battalions, each with three rifle companies organized into three rifle platoons. A mortar company, a machine-gun company, an artillery battery (company), and an antiaircraft artillery battery support the battalion, giving it a strength of 550 men. This is considerably less than the battalion strength of North Atlantic Treaty Organization (NATO) forces. Administrative and supply troops, such as ammunition bearers, drivers, and radio operators, are few in number, giving Soviet units less capability for sustained operations.

Weapons.—Modern Soviet doctrine includes the tactical employment of nuclear weapons. To develop such doctrine, numerous organizational tests have been conducted. No major overall changes have been made by the Soviets. The use of tactical nuclear weapons has made the importance of the infantry more manifest to Soviet leaders. Nuclear weapons have enhanced the part played by the foot soldier by raising his role to a new level. The Soviet Army infantry has been trained in means and methods of protection and in techniques of executing missions in the face of enemy nuclear weapons. New infantry equipment issued to Soviet units has improvements in mobility, firepower, and communications—all necessary for survival on the nuclear battlefield.

Tactics.—Soviet infantry attacks after thorough detailed preparations and thunderous artillery concentrations. Stress is placed on maintaining the momentum of the attack. Successive waves of troops moving forward relentlessly and with little regard to casualties produce assaults

that have a steam-roller effect. The result has been likened to a human sea directed against a chosen area in the enemy's defenses. The first wave bypasses strong points and strives to reach the objective quickly; the second wave reduces the bypassed strong points. Subsequent waves may be directed through the initial waves to maintain the momentum of the attack or may be directed to exploit success by flanking and encircling movements. The attacking waves are not mere skirmish lines, but have depth. The first wave of an attacking division frequently consists of three rifle battalions attacking over a frontage of one and one-half miles. These are reinforced by three more battalions. The second wave could then consist of the remaining three rifle battalions. Once the enemy defenses have been breached, the infantry destroys strong points in piecemeal fashion. As control becomes a complex problem, combat within the enemy's defensive position is the most difficult phase of the attack.

Soviet infantry defends in depth with a rifle battalion covering about one mile of frontage. Great reliance is placed on a powerful artillery effort in front of the main resistance zone. Counterattacks are stressed. Also emphasized is the ability of surrounded units to become self-sufficient and to break out of the encirclement.

The most significant change in the Soviet ground forces since World War II has been the great improvement in mobility and firepower. Armored personnel carriers are now in mass use, amphibious vehicles have appeared in large numbers, and helicopters are now widely employed. The Soviet Army arsenal features a new artillery system including field artillery, rockets, ballistic missiles of all ranges, and antiaircraft weapons of impressive mobility and effectiveness, together with a new family of tracked prime movers for their rapid emplacement and dispersal. The importance of armor-protected firepower on the nuclear battlefield has been recognized, and has resulted in the production of new amphibious medium and heavy tanks. Electronic equipment has been greatly improved, and modern communications equipment is in wide use throughout the ground forces.

Intensive training is employed to teach the troops to employ these new weapons under conditions of modern warfare. Soviet strategy and tactics have been modified to incorporate them. Current developments in Soviet tactics, weapons, and equipment reveal greatly increased emphasis on cross-country mobility, on mobile armored firepower, and on missile support.

Logistical support has been markedly improved by increased standardization of equipment and improved transport capabilities. It is now as mobile as the line divisions, and is believed capable of supporting them in every respect.

United States Reorganization.—The United States Army recognized after World War II that the use of tactical nuclear weapons would greatly alter tactics. It was faced with the problem of creating units and weapons capable of fighting a nuclear or a nonnuclear war. While the nonnuclear war was being waged in Korea, planners were developing an optimum nuclear battle force containing units capable of operating in widely dispersed formations, possessing increased mobility, equipped with organic nuclear delivery means, and having multiple means of communication and control.

Organization.—After numerous tests, the in-

fantry divisions were reorganized in 1957, and the triangular concept was completely abandoned. The reorganized divisions consist of 13,700 men as opposed to over 17,000 men in the older division. Yet the rifle or foxhole strength is increased. The basic infantry unit is a battle group of 1,400 men. Each division consists of five such groups. Each battle group now contains 5 rifle companies, each having 184 men. Each company contains three rifle platoons and a weapons platoon. The battle group is an integrated organization capable of operating semi-independently for short periods of time. In addition to rifle units, there is a combat support company providing organic heavy mortar support, antitank guided missiles, a ground reconnaissance capability (armored cavalry platoon), and ground surveillance radar. Engineer, medical, signal, administrative, and logistical support is furnished by the battle group headquarters company. Divisional units include a tank battalion, a reconnaissance battalion, and artillery with a nuclear capability in the Honest John rocket and the 8-inch howitzer. To increase ground mobility, two armored personnel carrier companies are organic to the division. These can transport one complete battle group or the assault elements of six rifle companies. The new division stresses flexibility of organization for combat and the need for formulation of mobile task forces tailored for specific missions. Each company is trained to have a motorized reinforced rifle platoon ready to move on 30 minutes notice to perform specific tasks. Movement by helicopter is emphasized, because it affords the greatest speed and freedom of action.

Reorganized Airborne Division.—The United States Army also reorganized its airborne divisions along similar lines. The airborne divisions consist of 11,500 men. Five airborne battle groups comprise the main infantry units. Each battle group has five rifle companies. To achieve complete transportability by air, tanks, antiaircraft, and heavy engineer equipment are not part of the division. This reduces the ability of the unit to maintain sustained combat for prolonged periods without augmentation. All personnel of the division are trained for parachute operations.

THE FUTURE OF INFANTRY

The stockpiling of thermonuclear weapons capable of yielding an explosive force equivalent to millions of tons of TNT (trinitrotoluene) has caused a small group of air theorists to declare that there is no need for the infantry or armies as part of the armed forces of the future. They hold that the existence of a strategic air force capable of prompt massive retaliation is the great deterrent to potential aggressors, but that, if war does come, the initial air attacks and counterattacks will determine the issue. Infantry advocates sharply disagree with this concept. Even if all-out nuclear war occurs—and this becomes less likely as nuclear parity between East and West approaches and the destructiveness of nuclear warfare becomes clear—the ultimate decision must be made by the infantry on the land. Infantry is the only force with the versatility required to gain control of the enemy's war-making potential: his land, people, and resources. The issues of war are decided on the battlefield regardless of whether this is the chief killing area. Decision in war is not obtained by counting the millions of dead or the number of devastated cities, but by subjugating the enemy force protecting the homeland.

Along with air and naval forces, the existence of combat-ready infantry forces by a nation or an alliance of nations, such as NATO, is an effective deterrent to potential aggressors. Their presence serves warning that aggression will be met on the land with force and that the aggressor must face the attendant risk. As the appreciation of all-out nuclear warfare becomes clear, the probability of such a total war decreases. Once war commences, the mission in the nuclear age is to localize the struggle, if possible, and to win the local war. If it cannot be localized, the mission is to win the all-out war. This can be accomplished only by infantry, supported by the other arms.

Every trouble spot, such as the Middle East, Indochina, Taiwan (Formosa), and Korea, has presented a special military problem. But these areas have had one common characteristic: any military action must be essentially a land operation.

The infantry of the future will be equipped with low-yield nuclear weapons and more effective nonnuclear weapons. It will be completely mobile, each unit having enough light, armored personnel carriers to carry all soldiers to the battle area as close to the enemy position as possible. To close with and to destroy the enemy in his defensive positions still will require the infantry to dismount from its carriers and to assault on foot. Infantry will be completely air transportable, to include all equipment and personnel. In a matter of hours, such a force could rapidly be transported by air to any trouble spot in the world. In addition, air vehicles will be used on the battlefield to preclude the necessity of negotiating difficult terrain and to assist in patrol- and raid-type operations in the enemy's rear. The battlefield will be fluid and, because of the increased lethality of weapons and the improved mobility of the infantry armies, may be smaller. The evolution of military weapons from the use of clubs to the use of tactical nuclear weapons has effected a tremendous change in the art of warfare. It has not altered the fact that man determines the final outcome of war. See also ARMY; TACTICS.

INFECTION. See BACTERIA AND BACTERIOLOGY—*Bacteria of Significance*; CONTAGION AND CONTAGIOUS DISEASES; DISEASE, GERM THEORY OF; STREPTOCOCCAL INFECTIONS.

INFERIORITY COMPLEX, ɪn-fēr-i-ōr'ī-tī kŏm'plĕks, a feeling of personal inadequacy induced by continued failure to achieve self-esteem. Awareness of physical defects, of an inferior social status, of difficulties in learning the curriculum, or of incompetence in meeting the problems of daily living may give the individual a sense of being inferior to others. Such handicaps may actually exist or they may be wholly imaginary. Familiar symptoms of an attitude of inferiority are the following: withdrawal from competitive endeavors, lest there be another defeat; a wish to "debunk" others, thereby lessening the need to be self-reproachful; an undue response to compliments and flattery, which seem temporarily to ease the tensions caused by the feeling of personal incompetence; and unjustified concern over well-intentioned criticisms. The individual with a feeling of inferiority is likely to misinterpret the behavior of other persons as being slights and

disparagements. Bizarre delusions of being persecuted by teachers, employers, friends, and associates may develop.

Repeated experiences with failures, especially during the early years of life, weaken whatever amount of self-esteem a child may have developed. Tasks which challenge the normal child are avoided by the one who has inadequate self-confidence. A succession of low marks in school, rejection by schoolmates, expressions of disappointment by the parents, unfavorable comparisons with a brother or sister—these are experiences which would inevitably lead to an attitude of inferiority on the part of a child. Lacking the psychological resources of an adult, the child is unable to construct a sense of justified confidence with which to face the world. The alternatives, then, are: (1) to rebel against the frustrations and to incur the risk of being defined as an incorrigible child; or (2) to accept defeat and to feel personally inadequate as compared to others.

Since the urge for self-respect is strong, the individual may develop compensatory behavior. For example, unable to win favorable attention through real achievements, the person may become boisterous, act in a clownish manner, or boast of imaginary superiorities. In a futile effort to find constant reassurance that there is no need to accept inferior status, the person may overmagnify the importance of membership in exclusive groups, of minor titles, or of some peculiar abilities. The "compensating intellectual inferior," for instance, strives to impress others through his use of polysyllabic words. Perhaps he hopes that, unlike Mrs. Malaprop (see MALAPROP, MRS.), he has correctly pronounced them.

INFERNO. See DIVINE COMEDY.

INFINITE, ɪn'fī-nīt (Lat. *infinitus*, unbounded, unlimited), in mathematics, a variable quantity which increases without bound or limit. In contrast with this, when a variable quantity decreases indefinitely, but never becomes zero, it is called an *infinitesimal*. Both of these concepts involve the idea of limits. For example, the quotient of a constant a by a variable x tends to become very large as x decreases to the value zero, and we write $\lim_{x \rightarrow 0} \frac{a}{x} = \infty$, which is read "as x

approaches zero as a limit, the value of $\frac{a}{x}$ increases without limit." In this sense the symbol ∞ (infinity) may be used to shorten a limit statement; but ∞ is an ideal number—it does not behave like an ordinary number in any sense.

In a series, like the geometric series, where each term is defined by a fixed relation to the preceding term, the number of terms is infinite. In geometry, a straight line may be considered as containing an infinite number of points, but between any two of these points there would be another infinity of points. Through any point may pass an infinite number of lines.

Many geometric ideas are simplified and broadened by postulating points, lines, and other geometric elements at infinity. Thus, two parallel lines meet in a *point of infinity* and two parallel

planes meet in a *line at infinity*. See also GEOMETRY, PROJECTIVE.

Professor Emeritus of Mathematics, The American University, Washington, D.C.

INFINITE, in philosophy. By the Infinite is usually meant an entity which neither begins nor ends in time and space and whose powers are limitless and self-caused. With exceptions, for example, Plotinus (205?–270 A.D.) and Baruch Spinoza (1632–1677), the Infinite has been identified with God, and in Western religious circles has been described as a He who cares rather than an impersonal It. Poets, philosophers, and theologians have expressed belief in the Infinite and have insisted that only knowledge of and emotional dependence upon or absorption into the Infinite can assure human happiness.

Plotinus emphasized that terms of ordinary language cannot be applied to the Infinite or, in his terminology, to the One. Similarly, medieval philosophers insisted that statements about the Infinite must be interpreted negatively, that the sentence "God is infinite" asserts primarily that finitude and limitation and imperfection are not to be attributed to God. Mystics have therefore sometimes tended to describe God as Nothingness, a description which has led some philosophers to conclude that nothing meaningful can be said about God or the Infinite.

The Infinite has also played a role in metaphysical discussions. Indeed, some philosophers still consider the task of specifying the relation between the Infinite and ordinary objects of limited duration, extent, and power, hence referred to as finite, to be the central problem of metaphysics. Naturalists, believing that only finite objects exist, refuse to recognize this as a problem; other philosophers insist that it is either an unclear or an insoluble one. To avoid these conclusions, Georg Wilhelm Friedrich Hegel (1770–1831) suggested that the finite and the infinite be considered not as distinct entities or realms, but as part and whole. He suggested that finite objects systematically interrelated over time form a system or whole, understandable only in light of the Infinite. Many, however, do not consider Hegel's reformulation helpful.

Whatever their logical status, speculations about the Infinite have generated many historically important hypotheses about the universe and its structure. Of particular interest are those ideas, traced back to Plato (427?–347 B.C.) by Professor Arthur Oncken Lovejoy (1873–), which center around the thesis that God, being infinite and devoid of meanness, has made the universe as complete and full as possible.

Entities other than supernatural or metaphysical ones have frequently been considered infinite, in either number, space, or time. The ancient atomists, for example, believed that the number of elements is infinite, a view which, if we allow the substitution of "elementary particle" for "atom," has been contested by contemporary scientists.

Beginning with Anaximander (611?–547 B.C.), some pre-Socratic Greek philosophers theorized about the existence of *to apeiron* (the boundless). For some this meant the postulation of an aboriginal indeterminate stuff out of which, through a variety of processes, familiar objects are gen-

erated; for others it involved belief in an infinitely extended entity. Aristotle (384–322 B.C.) argued against the latter thesis, insisting that no actual, as opposed to potential, Infinite can exist. His teachings, coupled with considerations from Ptolemaic astronomy, convinced many through the medieval and early modern periods that the universe was finite and had definite boundaries. Renaissance thinkers, including Nicholas of Cusa (1401–1464), Giordano Bruno (1548?–1600), and Thomas Digges (d. 1595), who in part revived arguments by Lucretius (94?–255 B.C.), challenged this tradition, which was all but abandoned by the 18th century, due to the influence of Newtonian mechanics.

Many of these discussions overlooked the distinction made in contemporary relativistic models of the universe between finiteness and boundedness. According to these models, the universe is finite in the sense that it contains a definite finite number of cubic miles, but unbounded, in the sense that it has no end or frontier.

Recent astrophysical theory is related to another time-honored problem about the Infinite, that is, the temporal infinity or eternity of the universe. According to Professor George Gamow (1904–), a time may be specified for the beginning or creation of the universe; hence the universe did not always exist. Professor Gamow's and allied theories, which incidentally are not universally accepted, are relevant for dating the universe as we know it, a universe in which objects and processes obey specifiable laws. What preceded the universe in this sense cannot currently be decided on scientific grounds.

On general considerations, one may agree with Immanuel Kant (1724–1804) and many other philosophers that reason cannot decide between the thesis that the universe is eternal and its contrary that there was an absolutely first event.

INFINITESIMAL CALCULUS. See CALCULUS—4. *Infinitesimals and Differentials.*

INFLAMMATION, in-flā-mā'shūn, the basic response of the animal body to any type of physical or chemical injury or bacterial invasion. This is the process by which the body, principally human, both resists and repairs damages caused by irritant forces: namely, heat, cold, radiation (X-ray, radium, or bomb blast), foreign bodies (a splinter), a bruise or direct trauma, chemical agents, electricity, pathogenic microorganisms, and, to a lesser extent, animal parasites.

The first clinical signs of inflammation are heat, swelling, and pain. Studies of blood vessel changes have been made by viewing through a cellophane or glass window microscopic sections of a living rabbit's ear, irritated by croton oil. The first reaction seen is the dilation of the arteries, veins, and capillaries, followed by a

rush of cells, particularly white blood cells, to the inflamed area. The force which summons the white blood cells has been called leucotaxine by Valy Menkin. Next the vessels are seen to release the white cells through their walls into the tissue space. Also released are certain portions of the plasma fluid, antibacterial toxins, large wandering cells, some red cells, and, later, small mononuclear lymphocytes. The polymorphonuclear leucocyte or ordinary white blood cell remains, however, as the foot soldier of the operation. Its duties include digestion of the invading bacteria by the process of phagocytosis. Many white cells are destroyed in the ordinary infection. Their debris forms the pus in the inflammatory exudate.

A classical example of an inflammatory change is the skin boil. Here the invading organism, the staphylococcus, causes the redness and swelling. The leucocytes are sent out to destroy the bacteria and to help to form the pus or core of the boil. At the same time the body is making an effort to rebuild the damaged tissue by the deposition of fibrin walls and the formation of fibroblasts. This step walls off the inflammatory area from the rest of the body and builds up a mechanical pressure inside the boil, which in turn ruptures toward the outside skin and drains. Thus healing is accomplished. It is an acknowledged fact that the bone marrow, when called upon by an inflammatory change anywhere in the body, will double or triple the production of leucocytes. This is why the normal white count, which runs between 5 and 10 thousand, may reach 20 or 30 thousand in, for example, an acute appendicitis, meningitis, or pneumonia.

Other cells in the areas of inflammation include macrophages, lymphocytes, and plasma cells. The macrophages are the large wandering cells with large arms (pseudopods) often originating in two or more directions to engulf foreign bodies, dead bacteria, and debris. The lymphocytes increase in number as the inflammation becomes more chronic, as in syphilis, sarcoid, or tuberculosis. Plasma cells, a type of lymphocyte, are seen in the exudate of chronic joint inflammations.

Inflammation is the first fundamental change of all pathological processes in the body, and is the key to both resistance and repair. The surgeon depends upon it to heal his operations. The physician would be powerless without its help, despite antibiotics, antisera, and vaccines which might be available.

REAUMUR S. DONNALLY, M.D.

INFLATION AND DEFLATION. Introduction.—Prices of nearly all goods and services have moved, at times violently, upward and downward in recent history. Most of the sharp increases in general prices have been associated with major wars. This was true of the price peaks attained in the United States at the end (or soon thereafter) of the War of 1812, the Civil War, World War I, and World War II. Price declines followed these spectacular upswings, but usually they fell short of the prewar levels of prices. Between wars, however, prices dropped to very low levels in the depressions of 1849, 1896, and 1932. Since World War II prices declined briefly in 1949, rose moderately during the Korean War, and then declined slightly to a relatively stable level until mid-1956. Subsequently, the main pressure seemed to be in the direction of rising prices. Other nations have

experienced similar price changes, and particularly since World War II have encountered rising price trends.

Meaning of Inflation and Deflation.—

In popular usage inflation means rising general prices and deflation, falling general prices. Greater precision of definition, however, is required in order to understand the complex movements of prices, general price changes and their effects, and the methods of controlling some kinds of inflation and deflation. First is the distinction between open and suppressed (or repressed) inflation that became significant in World War II and thereafter. *Open inflation* simply means an upward movement of the price level. *Suppressed inflation* refers to a situation in which an upward movement of the price level would occur if maximum limits established by law for prices, wages, rents, and the like were removed. Several kinds of evidence indicate this potential upward movement of prices. Long queues of shoppers waiting to make purchases, often without success, are common sights. This is true when stocks of goods available are much less than the amounts consumers are willing to buy at controlled prices, and are sold on a first-come-first-serve basis. To avoid some of the frustration and loss of time in shopping queues, rationing laws commonly are used that provide maximum limits for the amounts of certain things purchased per person per month, or other specified period. Also, government subsidies are paid sometimes for making certain essential commodities available at prices less than cost. And lastly, the prevalence of black markets in which buyers obtain illegally things at prices often greatly in excess of those stipulated as the maximum in legislation is definite evidence of suppressed inflation.

A second distinction relates to open inflation in which certain features of an upward price movement may vary significantly. One is the relation of total output in the economy to rising prices. If rising prices are encouraging an increase in output—a basic function of a price increase in a competitive market system—and thereby bringing about a fuller utilization of the labor force and production facilities, the situation may be termed *gross inflation*. Once the capacity of the economy is fully utilized, rising prices cannot bring forth additional output but only ration it to the highest bidders, and this situation is referred to as net or *pure inflation*. Another important feature is the rate and duration of an upward price movement. For instance, a gradual rise in the price level over a long period with approximately full utilization of capacity might be held by increasing productivity to an average of one per cent per year—a situation of *creeping inflation*. On the other hand, a sharply accelerating rise in the price level with approximately full utilization of capacity may within a year or two render money practically worthless and compel resort to awkward barter transactions—a situation of *galloping inflation* or *hyperinflation*.

Third, deflation is not the exact opposite of inflation. It is true that deflation involves a downward movement of prices, but usually any appreciable deflation is associated with increasing unemployment and lessening of output. This happens because a general decrease in demand for many goods and services lowers the price of some goods and services in competitive markets rather quickly with little change in output, but in monop-

olistic markets prices and wage rates tend to be maintained by reducing output and employment. On the other hand, prices can be raised much more readily than lowered, and although rising prices often increase output and employment (the opposite of deflation), one kind of inflation—pure inflation—does not. Moreover, in the process of deflation there is no counterpart to suppressed inflation.

Measurement of Inflation and Deflation.—

It is a relatively simple matter to describe inflation and deflation in terms of changes in the general price level and related conditions of output and employment. The measurement, however, of price-level changes and production-capacity utilization is difficult and unprecise—a circumstance, as indicated later, of considerable importance in controlling price-level changes. The level of prices, monthly and yearly, is expressed as an average which obviously cannot include all prices in such an average, so only a representative sample of prices is obtained. Not all prices move in the same direction at the same time—the price of automobiles may rise \$300 and the price of meat may fall 10 cents per pound. The influence of these diverse price changes of two unlike commodities on the price level depends on the relative change in the two prices and the importance or weight assigned to them in the price average. And lastly, over a period of time new products appear and old ones decline in importance, so that a revision of some items included in the average is necessary. When the prices of some commodities are eliminated and others are substituted the average is not measuring the prices of an identical group of items over a long period. However, a careful revision involves less inaccuracy in measuring price-level changes than continuation of items whose prices are no longer of any or very little significance.

Two examples of such averages for measuring price-level changes are the *Consumer Price Index* and the *Wholesale Price Index* of the Bureau of Labor Statistics of the United States Department of Labor. Other nations prepare and publish similar indexes. The *Consumer Price Index* shows changes in weighted average retail prices of selected goods and services (about 300 items: foods, apparel, housing, and other primary service items) considered important in the purchases of city wage-earner and clerical-worker families. These moderate-income families, which represent a large majority of people living in urban areas and a large portion of the total population, spend more on food than on apparel and more on housing than on service items. An average price change for foods, then, is more important in the cost of living than an equal change for apparel. Accordingly, weights are assigned to the different items in the index on the basis of their purchases by such families in 1952. The average level of prices of the 300 items, weighted to measure the purchases of middle-income groups, for the three years 1947–1949, is used as the base period and is designated as 100. When any other year's weighted average is divided by the average for the base period, the ratio (multiplied by 100) gives the relative price change, for example, 140 means that the average retail price is 140 per cent of the average price of the base period. Averages of prices for other periods are related proportionately to the base period of 100. The *Wholesale Price Index* uses the same years as a base period. Its monthly index includes prices of nearly 2,000

basic commodities charged by manufacturers or producers, or quoted on commodity exchanges weighted according to their sales importance in 1947.

The purchasing power of the dollar is measured in terms of both price indexes. The dollar buys less of the same commodities when wholesale prices rise and more when they fall. Thus, an index of purchasing power is the reciprocal of a price index. For example, a wholesale price index of 150 means that the price level increased 50 per cent as compared with the base period, and the reciprocal of this index, 66.7, means that the purchasing power of the dollar decreased 33.3 per cent, as compared with the same base period. Such changes in the value of the dollar for wholesale purchases are likely to reflect roughly its value for many other business costs. Also, the purchasing power of the dollar varies reciprocally in terms of retail prices paid by a representative group of consumers for the same selection of typical goods and services. These changes in the value of the dollar reflect generally for many families, changes in the cost of living for a specified standard of consumption—not higher or lower costs for raising or lowering one's standard of living. Both measures of the purchasing power of monetary units are commonly used, but often more emphasis is given to wholesale price indexes. This is preferred because of their broader coverage as compared with consumer price indexes, less difficulty in obtaining wholesale prices of things with and because of rather definite specifications, and the occasional use of government subsidies to depress arbitrarily the retail prices of some essential consumer goods.

Another important measurement consists of estimating the production capacity of an economy and its degree of utilization. This is important because pure inflation is defined as rising prices after full capacity output is reached, and a vital part of the analysis of the effect of inflation and deflation (beneficial or not) hinges on the degree of production-capacity utilization. Estimates of capacity are almost entirely in terms of the total labor force. Only for a few basic industries are there some statistics of plant capacity, but the amount of employment and unemployment in the economy is reported frequently. For instance, monthly sample surveys (Bureau of the Census, United States Department of Commerce) provide estimates of civilians 14 years of age or over who are employed (that is, at work, or with a job but temporarily absent), or unemployed (i.e., not working but seeking employment). Other civilians in this age group of the population are classified as "not in the labor force." The sum of the employed and the unemployed constitutes the civilian labor force. Usually the percentage of unemployment is used to indicate the degree of labor utilization and the approximate partial or full-capacity operation of the economy.

Explanations of Inflation and Deflation.—

The association of serious inflation with major wars is not accidental. Aggregate demand or total expenditures (consumer spending, business investment, and government spending) rise much more rapidly than output during a war period. This is particularly true of civilian goods which are likely to decrease in output as soon as war mobilization shifts substantial amounts of manpower into the armed forces and into industries producing war goods. The additional government

expenditures tend to expand output and total income (wages, salaries, profits, and the like) especially if some unemployment previously existed. However, nearly all of the additional government expenditures goes to a portion of those formerly employed in producing civilian goods and services in order to pay for war goods and services. This shift in the use of the labor force soon reduces the output of civilian goods, but maintains and increases total income. If the eliminated civilian goods have a value at prewar prices of say, \$50 billion, then a potential inflationary gap of approximately that amount exists. In other words, with income not reduced, the \$50 billion of income formerly spent on these eliminated items is available to be spent on the reduced output of civilian goods. When this gap is not closed by additional government taxes which absorb the excess income, or by government measures which prevent its being spent (price controls and rationing), prices rise rapidly.

Usually it is not feasible for a government in wartime to raise taxes quickly and sufficiently to absorb the excess income. Moreover, the net effect of new taxes on curbing spending is likely to be substantially less than the income diverted to government. Some individuals are likely to pay part of the new taxes by reducing the amount that otherwise they would have saved, and corporations are likely to set aside less for reserve. Consequently, governments resort to borrowing in order to finance a major portion of war expenditures. Such borrowing, of course, could close the inflationary gap, over and above the amounts diverted by new taxes, if the purchases of government bonds cut spending by a like amount. Many individuals may spend less and save more in order to purchase government bonds, but generally these individual savings reduce consumer spending only moderately, and are insufficient to satisfy quickly the government's needs for funds. To meet this emergency, modern governments, instead of printing additional paper currency, borrow heavily at banks in order to finance a large part of their war expenditures. In either case the inflationary result of more money and additional expenditures is approximately the same. The banks extend credit to the government in the form of demand deposits (checking accounts) in exchange for bonds. Government checks drawn against these deposits pay for goods and services purchased by the government, and those receiving government checks are likely for the most part to deposit them in their bank accounts and write checks to pay for what they buy. If some additional currency is needed by the commercial banks to cash checks, it may be obtained by drawing on their excess legal reserves and by their selling government bonds to the bank or banks authorized by the government (that is, Federal Reserve banks in the United States) to issue currency. Such banks may use in whole or part these bonds as a reserve against the issuance of additional currency. Furthermore, many firms receiving government contracts to furnish war goods borrow from the banks in order to convert and expand production facilities for this purpose. Thus, the total inflationary gap is the sum of government expenditures and business investment expenditures in excess of tax revenues and normal savings.

In a war period if direct controls (that is, legal limits on prices, wages, consumption, and the like) are not imposed, prices of civilian goods rise rapidly because of additional income that

can be spent on a reduced output. This generates a pressure for increase in wages and other incomes in order to offset the price rise of cost-of-living increase and to maintain approximately the previous level of consumption. Wage and other income increases are deemed necessary to provide incentives for production. For the most part these income increases do not help the recipients because no more goods can be made available, prices continue to rise—pushed upward by higher wage and other costs, and pulled upward by the expenditure of higher incomes. Costs of goods and services purchased by the government increase, and although tax receipts increase, additional borrowing is necessary to finance war expenditures. This inflationary spiral may continue until money becomes practically worthless, that is, prices may rise to thousands or millions of times prewar levels (for example, the German mark and the Russian ruble after World War I). On the other hand, at the end of a war, government borrowing to cover budget deficits may cease, and production of civilian goods may increase rapidly. These changes may halt the inflationary spiral at price levels anywhere between 50 and 1,000 per cent above prewar levels, and may bring about deflation (for example, the United States and the United Kingdom in 1920).

If direct controls are imposed, the basic shortage of civilian goods is not altered. Materials can be allocated to war industries and restricted for civilian production without substantial increases in prices. Maximum prices can be established for civilian goods at approximately prewar levels, and rationing controls can limit per consumer the amount of many essentials purchased so that the reduced output is shared more equitably. Such rationing and price controls of consumer goods prevent a sharp rise in the cost of living which makes feasible some control of wage increases. The cost of government purchases is curbed and less borrowing is necessary. Thus, the inflationary spiral may be largely suppressed. However, at the end of a war the inconvenience of direct controls to many consumers, their hampering effect on the resumption of peacetime production, and their cost of administration may lead rather quickly to their elimination. Prices may then rise moderately, although government expenditures are reduced and government borrowing is discontinued, largely because of greatly increased consumption expenditures and business investment. Unable to buy many things during a period of suppressed inflation and forced to save, consumers expand rapidly their purchases by using accumulated savings (for example, currency, bank deposits, and government bonds), by spending more and saving less of their current income, and by using installment and other kinds of credit. Expenditures for business investment are made to convert plant and equipment to peacetime uses, to buy new equipment, and to build up depleted inventories of raw materials and finished goods. These investments are financed mostly by accumulated savings and by borrowing at the banks. If the peacetime output of goods increases promptly in response to rising prices, the pent-up consumer demand is soon satisfied and further inflation is stopped.

Deflation is likely to follow a war period of open inflation. In this situation during a war prices rise so much that government expenditures and borrowing are excessive as compared to the war-production effort. At the end of the war

government expenditures fall rapidly, government borrowing is curtailed or eliminated, and prices begin to decline. Moreover, the open inflation of the war period reduces the ability and incentive of individuals to accumulate liquid savings (for example, currency, bank deposits, and government bonds), and hence, there is no appreciable increase in consumer expenditures at the end of the war to replace the decrease of government expenditures. And lastly, the initial decline in prices discourages business investment. Total expenditures, and consequently incomes, decline which reinforces the price decline, and the latter has further discouraging repercussions on investment expenditures. This is the deflationary spiral.

Deflation in an interwar period is sometimes complex in origin and difficult to explain. For instance, the great deflation or depression of the 1930's is explained in terms of several major "causes" and many minor ones. There is no complete agreement among experts concerning the explanation. Certain general features, however, seem to be typical of such peacetime, severe deflations. First of all, aggregate demand or total expenditures decline, not because of a cut in government expenditures and the development of a budget surplus, but because of a decline in business investment which creates unemployment and reduces income. Second, this initial decline in expenditures and in some prices (certain noncompetitive prices may be maintained or lowered very little by reducing output and laying off workers) generates further deterrents to investment expenditures until the construction and equipment industries practically cease to operate. Third, consumption expenditures decline, although prices are falling, because of increasing unemployment and the shrinkage of income. Eventually a bottom to the decline is reached when many individuals are using practically all of their current income for consumption expenditures in order to live, others are using up accumulated savings to avoid drastic drops in their consumption, and still others are depending on assistance from relatives, friends, and government to maintain a minimum level of consumption. When the decline of consumption expenditures is arrested, prices stabilize and soon rise because of the resumption of business investment, perhaps augmented by an increase in government expenditures and borrowing. Fourth, the rise in investment occurs because eventually some plant capacity becomes unusable and obsolete and new equipment is needed for current operation and for prospective replenishment of depleted inventories.

The falling off of business investment at the beginning of a decline in some prices seems to be the origin of the ensuing deflationary spiral, but the probable conditions responsible for it are multiple and not single. Just prior to the break in prices it is probable output, employment, and income may have been increasing because of technological improvements in certain industries and profitable innovational opportunities which encouraged directly some investment, and also indirectly induced investment in other industries. Part of this investment expansion is likely to be financed with bank credit. Total expenditures rise, prices rise, and the demand for labor increases wages. Gradually profitable investment opportunities become fewer in number and the banks become less willing to extend credit. Rising interest rates, wages, and costs of capital equipment narrow amount or rate of profit. In a few

industries expansion of output may lower a few prices although most prices are still rising. Because of the upward trend in prices, many speculative purchases of commodities, securities, and real estate are made, in part with bank credit, in anticipation of further increases. And lastly, although consumption expenditures increase with rising personal income and prices, the customary percentage of income saved means a rising volume of savings. Thus, when the inducement to invest weakens and the rate of investment expenditures lessens, intended savings will exceed intended investment and the excess will not be returned to the flow of income. The shrinkage of income retards the sale of consumer goods, results in unexpected accumulation of inventories, and depresses many prices. A process of liquidation begins—an increasing pressure to sell inventories, securities, real estate, and the like in order to restrict losses and to meet debt obligations which forces further liquidation because of falling income and prices (foreclosures and sheriff's sales).

Effects of Inflation and Deflation.—A rising price level results from increasing total expenditures and income. If all prices rose in the same proportion and if various kinds of income increased in a similar fashion, most of the disrupting effects of inflation would not appear. But this does not occur. Some money incomes rise slower (a few not at all) than the cost of living, and others faster. The former includes rentals (usually subject to long-term contracts), pensions, annuities, interest yields on bonds, and certain wages and salaries (for example, employees of state and local governments, schools and universities, hospitals, churches, and charitable institutions). Individuals depending mainly or entirely on such income, lose from inflation—their real incomes decrease. On the other hand, stockholders and other owners of business enterprises are likely to gain from inflation. As sales receipts increase from higher prices some costs tend to lag behind, and hence many profit incomes rise faster than the cost of living. Also, professional persons in independent practice and members of labor unions having great bargaining power usually experience a gain in real income.

Inflation not only alters the distribution of income, but also the distribution of wealth. Since rising prices mean decreasing purchasing power of money, many debt obligations contracted for a period of years involve a loss for creditors and a gain for debtors. For instance, a purchaser of a \$10,000 house obtains mortgage credit of \$8,000 to buy it. At the end of say five years only a few hundred dollars of the loan are repaid, the price level is doubled, and the owner sells the house for \$20,000. The creditor receives his loan of \$8,000, but its purchasing power is now only \$4,000—a loss of \$4,000. The debtor-owner receives \$12,000, or \$6,000 in current purchasing power—a gain of \$4,000 over his equity investment of \$2,000. Other kinds of creditor claims or assets fixed in terms of money, such as savings accounts, life insurance policies, and bonds decline in value because of inflation and the fall in the purchasing power of money. On the other hand, inflation increases the value of many kinds of ownership equities in buildings, land, unincorporated enterprises, and corporations (shares of stock).

Thus, because of inflation some groups in the economy lose in terms of income position and

creditor-debtor relations, and others gain. However, the kind of inflation is important in analyzing the overall effect. When rising prices reduce mass unemployment to a very small percentage and increase output substantially, the gains of inflation probably exceed greatly the losses. The increase in output moderates the rise in the price level, and hence the losses in real income and creditor status of some individuals. Perhaps a few individuals neither lose nor gain, but many are likely to gain—those having income increases greater than the price-level increase, debtors, and the mass of workers formerly unemployed. Also, the removal of serious unemployment lessens social and political tensions which may contribute to violence and general disregard of public law and order. In sum, this is a situation in which nearly everyone can be better off without making very many worse off.

The inflationary situation is quite different when the price level continues to rise after approximately full employment is attained and output no longer increases. Such pure inflation is likely to inflict severe hardships on many individuals whose money incomes are relatively fixed, and substantial losses on those having an important creditor status. Also, the relatively high prices discourage exports and encourage imports with a consequent loss of monetary reserves (mostly gold) in order to pay for the import excess. To cope with this adverse change in international economic relations, governments in modern times establish elaborate and costly foreign exchange controls. These controls, supported by heavy penalties, force exporters of a nation to exchange their receipts in a foreign money at a fixed rate for domestic money, and limit importers' purchases (kinds and amounts) so that there is no excess of imports over exports. When pure inflation reaches a hyperinflation stage, chaos ensues and total output decreases. Economic processes are disrupted and retarded because of speculative hoarding of raw materials and inventories, and the reversion to primitive barter for many transactions. Farm produce, for instance, is mostly exchanged, not for money, but for other goods. Many individuals barter their services and personal possessions in order to obtain food and other essentials. Many creditors are impoverished by receiving payment of loans in practically worthless money. Money income is spent as soon as possible after it is received in order to minimize loss of purchasing power because of rapidly rising prices. Hyperinflation usually ends by government action abolishing the old monetary unit and establishing a new one—existing currency and bank deposits becoming worthless, or being convertible in terms of the new money at a very low rate.

Suppressed inflation is usually less disadvantageous than open inflation particularly during a war emergency. However, even when it is a virtual necessity and is supported by war patriotism, there are adverse effects. The prices of many essential consumer goods are held down, but the distribution of ration coupons to limit purchases cannot avoid some inequities on the basis of individual and family needs. If at different times ration coupons are in excess of goods being made available, much time is lost in repeated shopping trips and waiting. Also, without frequent and costly rearrangement of maximum consumer prices, producers will shift output to more profitable items and neglect others so that

rationing control is in part defeated—some items are seldom available. Moreover, it is not feasible to control firmly the prices of many farm products, partly because production is discouraged. When some maximum consumer prices are raised, particularly those of foods, then ceilings on wage rates must be allowed to rise as compensation for the higher cost of living in order to maintain workers' energy and morale. But higher wage costs are likely to lessen the output of some consumer goods. Maximum prices can be set for raw materials and other producer goods, and priorities can be assigned to firms for their purchase (producer allocation or rationing), but these measures do not assure prompt delivery of the kinds and quantities of things to which firms are legally entitled. These maladjustments distort and hinder production. Illegal sales (black markets) of both producer and consumer goods flourish in spite of heavy penalties imposed on violators who are arrested. And lastly, when direct economic controls are extended beyond a war period to suppress inflation, the foregoing adverse effects are greatly magnified. In particular, the incentive to produce is weakened and patriotic appeals are ineffective. Although money wages are allowed to rise, price control and rationing force an increase in savings which soon becomes an unsatisfactory substitute for additional consumer goods even at higher prices. Workers unable to spend their wages for many things greatly desired develop a high rate of absenteeism on jobs, refuse overtime work at premium rates, and experience a deterioration in morale.

The effects of deflation may be stated briefly since they are mainly the opposite of inflation. During a decline in the price level, some prices and incomes decrease much less than others. Individuals depending mostly or entirely on rental income, pensions, annuities, interest yields on bonds, and certain wages and salaries gain from deflation—their real incomes increase. Stockholders, other owners of business enterprises, and professional persons in independent practice generally experience a decrease in real income from deflation. Concerning creditor-debtor relations fixed in terms of money, such as mortgages, savings accounts, life insurance policies, and bonds, deflation increases the purchasing power of creditor claims and imposes a burden on debtors to make repayments in money of greater purchasing power than that originally received. Also, deflation reduces the value of many kinds of ownership equities in buildings, land, unincorporated enterprises, and corporations.

In any deflation some groups in the economy lose in terms of income position and creditor-debtor relations, and others gain. The overall effect depends on changes in output and employment. For instance, a moderate decline in the price level which eliminates pure inflation without reducing an approximately full-employment output is likely to involve gains in excess of losses. A similar beneficial, overall effect appears when a mild deflation is the result of increasing productivity and is gradual enough to avoid more than a very small percentage of unemployment. But the deflationary situation is quite different when declining prices result in widespread business failures, extensive foreclosures of mortgaged farms, mass unemployment, and substantial reduction of total output—a

situation in which nearly everyone loses and only a very few gain. Because of bankruptcies and forced sale of mortgaged properties, some creditors as well as debtors lose. The losses incurred by mass unemployment (economic, social, and individual morale) cannot be measured, but they are so great that many modern governments try to prevent such a catastrophe. They use indirect economic controls—government expenditures and borrowing, and bank-credit measures—to offset any serious increase in unemployment. Also, they provide unemployment compensation and other aids to alleviate the hardships of those who become unemployed, and to maintain consumption expenditures.

Stabilization of the Price Level and Full Employment.—Many governments, particularly since World War II, try to stabilize the price level and at the same time to maintain a high level of employment. Certain control measures are used to offset deflation when employment declines appreciably below full employment, and to curb inflation once full employment exists. In the former instance government measures can be used to encourage business investment and consumer expenditures; namely, to have the central banking system (government owned or controlled) lower its interest rate on loans to commercial banks and provide other assistance so that they can make more credit available at lower interest rates to business enterprises and consumers. If such encouragement is insufficient to increase aggregate demand to a full employment level, then a direct increase in government expenditures and borrowing is used to raise aggregate demand. An increase in expenditures for public works and social services can be accompanied by a reduction in taxes, the deficit being financed primarily by the sale of government bonds to the central banking system. Aggregate demand for output is increased by the additional government expenditures, and the tax reductions free some private income for additional business investment and consumer expenditures. Such measures when applied firmly seem adequate to offset deflation and to restore approximately full employment. Popular support for a government program of lower interest rates, greater availability of credit, increased government expenditures and lower taxes is usually forthcoming.

To curb rising prices or inflation once full employment is attained, the above control measures are reversed. Interest rates are increased and credit is restricted in order to discourage business investment and consumer expenditures. Sometimes special regulation of consumer installment credit and mortgage credit for new houses is added. Government expenditures are reduced to curtail one segment of aggregate demand, and taxes are increased to reduce indirectly the other two segments, business investment and consumer expenditures. Effective tax curbs include increases in the rates imposed on business incomes, decreases in exemptions allowed for personal income taxation, and higher excise and sales taxes. The latter may tend in part to enter into the cost of living indexes, and thus automatically raise some wage rates covered by labor contracts providing cost-of-living increases. These measures can eliminate government borrowing and produce a budget surplus. Many difficulties, however, are encountered in applying such inflationary curbs and at the same time trying to maintain full employment.

One difficulty is the inexact nature of the statistics of employment and unemployment as already noted. This means that the size of the civilian labor force and its degree of utilization, partial or full employment are not precisely known at any time. Moreover, in using the available statistics it is recognized that some percentage of unemployment will probably persist although rising prices approach a stage of pure inflation. This circumstance arises because as aggregate demand increases and the amount of unemployed labor and unused production facilities shrinks to a very small percentage, shortages appear at some points in the production process and surpluses at others. The increase in aggregate demand is not spread evenly over the economy, and if it were, changes in production techniques alter labor and capital requirements in various industries. In some areas there is unemployment and unused plant capacity, but these unemployed workers cannot be quickly and easily transferred to areas having unfilled jobs, nor can unused plant capacity be quickly converted (if at all) to other kinds of output in great demand. If unemployed workers were able and willing to move quickly to unfilled job areas, their skills may not fit in many cases the job requirements, and hence retraining of old workers and training of new workers are necessary before certain kinds of outputs in great demand can be increased. The temporary failure of some outputs to increase, such as materials and equipment used by other industries, retards production and lessens employment in other parts of the economy. Such frictional unemployment, as it is called, is always present in the economy.

In general, then, as aggregate demand increases and unemployment falls to a small percentage, some outputs cease to expand appreciably, but their prices continue to rise; and other outputs continue to expand at slower rates, higher costs, and higher prices. Strong labor unions obtain wage increases in excess of productivity increases, and semimonopolistic firms raise prices to maintain or increase profit margins. Because of the tight labor market, other workers in industry, trade, and services obtain wage increases to offset the rising cost of living which are in excess of productivity increases. Primarily, rising costs push, and secondarily, rising incomes pull, prices upward. Soon a point is reached when increasing aggregate demand results in major price increases and only in minor output increases, but frictional unemployment still persists and is likely to persist until pure inflation occurs. Thus, another difficulty of curbing inflation and maintaining "full employment" is the determination of the critical point at which the losses of many individuals from price-level increases are greater than the limited gains in output and employment, and at which the wage-profit-price spiral suddenly explodes into pure inflation.

Presumably some latitude should be permitted in the stabilization of the price level and in the maintenance of full employment. However, policy concerning the range of permitted fluctuations is a matter of controversy. Since the exact amount of irreducible, frictional unemployment cannot be calculated, there is disagreement as to whether inflationary curbs should be applied to rising prices when unemployment is (say) 5, 3, or 1 per cent of the civilian labor force. One suggestion is that such curbs be applied lightly, if at all,

to rising prices when some unemployment exists, as long as the percentage increases in total output are in excess of the percentage increases in the price level. Clearly, if inflationary curbs are imposed too early (say at unemployment of 5 per cent) and too drastically, deflation and widespread unemployment may quickly develop. On the other hand, if such curbs are imposed too late (say at unemployment of 2 per cent) and too mildly, pure inflation may quickly develop. Because of these uncertainties, difficulties, and other pressures, governments now attempt mostly to hold inflation on the average to a creeping rate. This policy encourages a high level of employment as the labor force grows in size, stimulates investment, brings some increase in total output, and lessens the burden of government debt. Apparently, it wins popular support. A program for halting creeping inflation involves higher interest rates, credit restriction, reduction of government expenditures, and higher taxes, and is not likely to generate political support. Small firms, for instance, are generally more dependent than large ones on the use of bank credit, and they object to higher interest rates and restriction of credit. Restriction of consumer installment credit and mortgage credit for new houses is opposed by many consumers and by the suppliers of consumer durable goods and houses. A reduction of government expenditures may be generally approved, but there is bitter conflict concerning specific cuts in expenditures particularly when they affect certain areas of, or groups in, the economy more than others. And lastly, increases in taxes are seldom popular, and sharp controversy develops concerning the kinds and amounts of tax increases—whose taxes are to be increased and how much.

Thus, some creeping inflation and maintenance of a very high level of employment seem to be preferred, or tolerated, as compared with approximate stabilization of the price level at a somewhat lower level of average employment. In time a satisfactory compromise between these alternatives may be achieved. Special government programs may be developed to reduce frictional unemployment to a very moderate percentage, and unemployment compensation may be increased to eliminate the hardships of such unemployment, and any other unemployment created temporarily by inflationary curbs to achieve approximate stabilization of the price level. Perhaps selective controls of interest rates and the availability of credit may be arranged so that any restriction will affect more equitably firms of various sizes, different groups of consumers, and certain kinds of essential public investment (for example, schools) as compared with many kinds of private investment. However, since World War II nearly all governments appear to follow a common policy; namely, that adequate inflationary curbs can halt increases in the price level only by depressing substantially the level of employment and output, and that existing measures to offset and alleviate the effects of this deflation are insufficient to make such a program politically feasible. The history, therefore, of price trends in most nations in recent years is one of varying degrees of inflation.

Price Trends in the United States.—For more than a decade before World War I prices were slowly rising in the United States, but the open inflation of the war period radically changed this trend. The index of wholesale

prices more than doubled from 1914 to its postwar peak in 1920, and the consumer price index (cost of living) also doubled. During the same period the average weekly earnings of workers in manufacturing industries increased somewhat more than the cost of living. In 1920 a deflation began which lowered wholesale prices in an irregular fashion to a record low in 1932—slightly below the level in 1914. Prices of farm products declined more than those of industrial products. However, the decline in retail prices reflecting the cost of living was substantially less than wholesale prices, and at the low point in 1933 the consumer price index was almost 30 per cent above the 1914 level. During this period (1920–1933) the average weekly earnings of workers in manufacturing industries declined slightly more than the cost of living, but at their low point in 1933 were about 50 per cent higher than in 1914. This represented a gain in real wages for those employed, but in 1933 approximately 25 per cent of the civilian labor force was unemployed—a record low as compared with 1920 and 1914.

After the great deflation or depression in 1932–1933, wholesale and consumer prices in the United States rose generally, including the suppressed inflation of World War II, with only a few brief and slight declines in 1938–1940, 1949, and 1952–mid-year 1956. During the latter period wholesale and consumer prices remained relatively stable—the decline in the prices of farm products and processed foods more than offset the price rise for some industrial products in the wholesale index, and the decline in consumer-commodity prices approximately offset the rise in consumer services and rent. However, in January 1957 the wholesale price index reached a record high—about 133 per cent above the pre-World War II level of 1939, and almost 17 per cent above the previous peak of 1920. Between 1939 and January 1957, prices of farm products increased (with a few temporary declines) somewhat more than those of industrial products. The consumer price index (cost of living) also reached a record high in January 1957—about 99 per cent above the pre-World War II level of 1939, and 38 per cent above the previous peak of 1920. The average weekly earnings of workers in manufacturing industries in January 1957 were 245 per cent above the pre-World War II level of 1939; industrial production, about 152 per cent above the 1939 level. In January 1957 only 4.5 per cent of a much larger civilian labor force was unemployed as compared with approximately 17 per cent in 1939.

Thus, in the United States the second great inflation of the 20th century. World War II and its aftermath, approximately doubled the price level. The purchasing power of the dollar at the beginning of 1957, as compared with 1939, was slightly less than one half in terms of the wholesale price index and only fractionally more than one half in terms of the consumer price index. However, during this period, total output, income, and population increased greatly. When allowances are made for the increase in prices, total output (gross national product) was 110 per cent greater at the end of the period than in 1939, and about 70 per cent greater on a per capita basis; and total disposable personal income (personal income less personal taxes) was 108 per cent greater or about 62 per cent on a per capita basis. This means that a substantial in-

crease in real income occurred—the increase in goods and services and in money incomes more than offset the rise in prices. The purchasing power of the dollar declined approximately 50 per cent, but the spending power of consumers per capita increased 62 per cent. Since the amount of unemployment in January 1957 was much less than in 1939, and since disposable personal income was more equally distributed, the increase in real disposable personal income per capita reflected a substantial improvement in living conditions for most individuals and families. Of course, the gains and losses experienced by different groups during the process of inflation (1939–January 1957) are not revealed in the above comparisons. Moreover, there is uncertainty concerning future price trends. In order to curb rising prices in 1956–1957, interest rates were raised to the highest level since 1933 and some effort was made to prevent an increase in federal government expenditures.

Price Trends in Canada.—Inflation in Canada since 1939 followed a pattern similar to that of the United States. After World War II price and wage controls were terminated in 1947, about one year later than in the United States. Between 1939 and early 1957 the level of wholesale prices more than doubled, an increase of 131 per cent as compared with 133 per cent in the United States. The index of consumer prices (cost of living) almost doubled, but showed an appreciably smaller percentage increase (90 per cent) than that of the United States (99 per cent). Average weekly earnings of workers in manufacturing industries increased about 196 per cent, and at the end of 1956 only 3 per cent of the labor force was unemployed as compared with an estimate of 12 per cent for 1939. During the period total output, income, and population increased. When allowances are made for the increase in prices, total output (gross national product) was 141 per cent greater in 1956 than in 1939, and about 70 per cent greater on a per capita basis; and total disposable personal income was 150 per cent greater or about 76 per cent on a per capita basis. This represented a substantial increase in real income for consumers—76 as compared with 62 per cent in the United States. However, the appreciable rise in prices in 1955 and 1956 induced the government to raise interest rates and restrict credit in an attempt to halt inflation.

Price Trends in the United Kingdom.—Inflation in the United Kingdom since 1939 followed a somewhat different pattern from that of the United States and Canada. Price controls were not terminated until 1953, and some rationing of food was continued until the middle of 1954 which marked the end of 14 years of rationing. Between 1939 and early 1957 the level of wholesale prices more than doubled, which involved a percentage increase slightly greater than that of the United States and Canada. During the same period the index of consumer prices (cost of living) almost doubled, but showed an appreciably smaller percentage increase than that of the United States, and approximately the same increase as in Canada. Government subsidies, however, for housing, bread, and milk held the rising cost of living partly in abeyance. Average earnings per hour in manufacturing industries increased more than 230 per cent. At the end of 1956 about 1 per cent of the labor force was unemployed, and a

larger total output and money income provided a moderate increase in real income. Because of the appreciable rise in prices in 1955 and 1956, the government increased substantially the bank rate of interest, imposed selective credit restrictions on installment buying, levied higher taxes on the purchase of consumer durable goods, and reduced some government expenditures. In September 1957 the bank rate of interest, increased from 5 to 7 per cent, was at the highest level it had reached in the United Kingdom since 1920.

Price Trends in France.—Inflation in France since 1939 approached a stage of hyperinflation. Although some price, wage, and credit controls were used in the postwar period, they could not overcome the great disruption of economic processes which occurred during the war and enemy occupation of the country. Government borrowing, mainly from banks, was used to meet expenditures in the postwar period. Between 1939 and early 1957 the level of wholesale and consumer prices (cost of living in the Paris region only) increased more than 2,000 per cent, or 20-fold. Some government subsidies continued to depress arbitrarily the cost of living. Average rates of pay per hour in manufacturing industries increased almost 2,500 per cent. At the end of 1956 probably less than 1 per cent of the labor force was unemployed, and total output was larger than in 1939. However, the increase in real income of consumers was very moderate. In 1956, after three years of relative price stability, further price increases induced the government to impose additional restrictions on credit, raise some taxes with the hope of lessening the budget deficit, and to freeze industrial prices. The government in 1957 intensified efforts to suppress the upward adjustment of some prices and wages. It also adopted the equivalent of a 20 per cent devaluation of the franc. In sum, a situation of suppressed inflation continued. See also GOLD STANDARD, THE; PRICES.

INFLECTION, ĭn-flek'shŭn, a grammatical term used in describing the different forms by which a word may indicate such systematic variations of meaning and function as those of case, person, number, and tense. (See GRAMMAR.) For example, Latin *amo* "I love," *amas* "you love," *amat* "he loves"; English *love*, *loved*, *loving*. The word *inflection* is an inheritance from the Roman grammarians (for example, Donatus: *pronomina inflectuntur hoc modo* "pronouns are inflected in this way"), for whom in turn it was a translation from the grammatical terminology of the Greeks. The Greek grammarians thought of one form—the nominative in nouns and the present in verbs—as being "normal" or "unmodified" and of the others as "turning away" or "bending down" from it. Therefore the Romans used the word *inflectare*, "to bend down." Similarly, the word *casus*, our word *case*, meant "the

act of falling"; the Romans distinguished *casus rectus*, the "upright" case, from *casus obliquus*, the "inclined" case, hence our term oblique case, meaning any case other than the nominative.

Not all languages have inflection. Even those that are genetically related may differ considerably, for the amount of inflection may change during the history of a language. Among the Indo-European languages, English has two forms for the singular of the noun, nominative *boy* and genitive *boy's*; Latin has five; Sanskrit, eight. The declension of the adjective is a striking example of loss of inflection in English. Modern English has only the one form *good*, but the Old English of a thousand years ago had nominative *god*, genitive *godes*, dative *godum*, accusative *godne*, and instrumental *gode*. On the other hand the case system of Hungarian seems to be expanding through the specialization of a number of postposed suffixes, which are already classed as case endings by some authorities. Furthermore, for many languages the whole idea of inflection is irrelevant, since they have completely different methods for indicating variations in meaning and function (see *LANGUAGES OF THE WORLD—Methods of Classification*).

The particular role of inflection varies considerably from language to language, but in general the inflection of a word helps to show to what part of the morphological system it belongs. In many languages, as in English, it is possible to make changes in meaning or function systematically by changing the form of the word rather than by using an additional explanatory remark or a different word altogether. Here again some languages have more elaborate morphological systems than others. To express number, English has two systematic possibilities—singular *bird* and plural *birds*, and many that are nonsystematic: *two birds*, *many birds*, *few birds*, *a flock*, and so on. In classical Greek this section of the morphological system was fuller by one degree: *ornis* "bird" and *ornithes* "birds," but also *ornithe* "two birds."

As inflection disappears from a language, other devices assume its function. Characteristic is the English use of word order. In the sentence *The boy gave the dog a bone*, the nouns do not differ in inflection, yet the function of each is made clear by its position in the sentence. *Boy*, which would have the special ending of the nominative case if the sentence were written in Latin, is shown to be the subject by being placed before the verb; *dog*, dative in Latin, is the indirect object, placed first after the verb; and *bone*, accusative in Latin, is the direct object, being the second noun after the verb. Any interchange in the position of these words would give either a different meaning or nonsense.

Some scholars have speculated on the problem of just what amount of inflection makes a language the best vehicle of communication, but except for an understandable tendency for each to rate his own type of language highest, there has been no considerable agreement.

WILLIAM DIVER,
Department of Linguistics, Columbia University.

INFLORESCENCE, INFRUCTESCENCE, botanical terms referring respectively to methods of flowering and fruit bearing. The flowering shoot frequently bears only a solitary, either axillary or terminal flower. In many

cases, however, the metamorphosis of the generative region, which results in the production of flowers, has led to the formation of a special system of fertile shoots termed an inflorescence or, after the fruit is formed, an infructescence. (See *FLOWERS*; *FRUIT*.) Such inflorescences are wanting or ill developed among the gymnosperms, while in the angiosperms they are often well differentiated, constituting unities of a higher order. The modifications exhibited by the fertile shoots of such an inflorescence are due, partly to a difference in their mode of branching, partly to the reduction of the metamorphosis of their leaves. These changes are the result of an adaptation to pollination, in the endeavor to aggregate and at the same time render the flowers more conspicuous by the reduction of the foliage leaves. Sometimes the whole system of fertile shoots is converted into an attractive apparatus, as in the *Araceae*, where the axis and the subtending leaf of the inflorescence have assumed the function, usually exercised by the perianth, of enticing insects.

The solitary flower excepted, the principal types of inflorescence are called *racemose*, *cymose*, and *mixed*. Representative of the racemose are the lily of the valley (raceme) and the cherry (corymb); of the cymose, the phlox (cyme); and of mixed type, the form called thyrsus in which the main axis is racemose, while secondary and later axes are cymose. Another mixed type is the verticillaster in which nearly sessile cymes in pairs surround the axis.

INFLUENZA, in-flō-ēn'zā, an acute infectious respiratory disease caused by a specific group of viruses. It is highly transmissible spreading with extraordinary rapidity in sporadic, epidemic, or pandemic outbreaks. The disease is characterized by sudden chills, fever, headache, muscular pains, and prostration. The name "influenza" (Ital. influence) reflects the fact that it was once thought to be due to the influence of the stars upon man. The popular terms "flu" and "grippe" should likewise be restricted to this disease, and not applied to common respiratory diseases with systemic manifestations.

The first recorded epidemic of influenza occurred in Italy, Germany, and England in 1173. This was a mild infectious invasion, but the first pandemic in 1580 resulted in the death of thousands daily. The term "influenza" first came into common English usage during the European epidemic of 1743, which was followed by 24 pandemics in all continents, increasing in frequency and severity until the 1918 pandemic, which cost 30 million lives. The gradual decline in incidence and severity of the disease is manifested by progressively shorter peaks of invasiveness and lower troughs of mortality. A marked rise in the influenza mortality of the older age group from 25 per cent in 1918 to 88 per cent in 1951 is attributable to underlying chronic degenerative diseases.

Types and Diagnosis.—The riddle of the causation of influenza was solved by the British bacteriologist Wilson Smith in 1932 with the demonstration of influenza A virus in throat washings of afflicted patients, who revealed specific antibodies during convalescence. Later, the American, Thomas Francis, isolated the influenza B virus and its antibodies in patients during the 1940 epidemic; Richard Moreland Taylor, the influenza C virus in the 1949 epidemic; and A.

Sendai, the influenza D virus in the 1953 epidemic in Japan. The alphabet designation merely represents the order in which the viruses were discovered. They are all about 100 millimicrons in diameter, visible as a sphere or filament by the electron microscope, and showing marked affinity for the respiratory epithelium of mammals. Infection with one type of virus confers no immunity against any of the others, and that produced is temporary in contrast with other viruses such as measles, smallpox, and yellow fever, whose attack leads to a permanent change in the attitude of the host.

Influenza A epidemics start abruptly, reach a peak in two weeks, and subside rapidly after attacking about 40 per cent of the urban population, appearing simultaneously in widely separated areas as minor respiratory infections. The virus becomes widely seeded in avirulent form during the summer months and remains dormant until cold weather precipitates outbreaks at many foci, its virulence increasing with the rapid spread of the infection in susceptible individuals. Influenza A virus causes major winter epidemics, which recur at two- to four-year intervals as a result of the decline in the effective immunity of a population and the emergence of new virus strains. The influenza that prevailed between 1933 and 1945 completely disappeared but was replaced by four new serologically intersecting groups designated as influenza A', with marked changes in antigenicity, isolated in epidemics in South Africa and Australia (1950), England (1951), and Europe, Japan, and the United States (1952). Striking changes in the strains of influenza A' virus were subsequently detected in China in 1957, in the virus responsible for the Asian pandemic.

Influenza B and C occur sporadically in schools and camps, the former at four- to six-year intervals and the latter at any time. Influenza A causes typical pandemics, influenza B, moderate epidemics; and influenza C, mild outbreaks.

The diagnosis of influenza is easy during epidemics but difficult during endemic attacks. Each of the four viruses produces a clinical picture ranging from mild infection to severe prostration complicated by pneumonia. Influenza A is accompanied by a more definite pattern of symptomatology than influenza B, but there are no means of clinical differentiation without laboratory studies. The causative influenzal virus can be isolated within five days by inoculation of the acute nose and throat secretion into a chick embryo, and later by the demonstration of a significant rise in serum antibody titers produced by known influenza virus antigens during the convalescent stages.

Spread and Course of Disease.—The origin of an epidemic depends on the appearance of a new strain of virus arising locally or introduced from without, and with sufficient capacity to spread. Attack rates of influenza vary from 1 per cent to 20 per cent, being lowest in sparsely settled communities and highest in congested areas. The virus is maintained by sporadic cases during intervals between epidemics. Droplets from an infected nose and mouth reach susceptible individuals via the respiratory tract. Attacks are usually mild because most individuals over five years of age have antibodies against influenzal viruses, although specific immunity after an attack lasts only about eight months because of the localization of the infection to the respiratory mucous membrane. Specific immunization is pro-

portional to the level of the serum antibody titer, but influenza may attack individuals with high antibody levels.

The incubation period of influenza is generally 18 to 36 hours but may be as long as 72 hours. Mild prodromal manifestations of malaise, chilliness, and cough may appear, but the extremely sudden onset enables one to recall its exact time. The frontal headache is accentuated by upward gaze, and diffuse aches in the back and legs limit movement. There may be faintness and dizziness from the onset followed by feverishness and chilliness. The fever rises abruptly to about 103° F. several hours after the onset and occasionally to 106° F. Both fever and pain generally subside after two or three days but may persist for weeks, with a secondary rise of fever after subsidence.

The severity of influenza parallels the height and duration of the fever. Respiratory manifestations develop when the fever subsides, or they may be entirely absent. Such manifestations include sneezing, nasal discharge, blocked breathing, dryness of the throat, hoarseness, and nosebleeds. Some cases reveal itchy, watery eyes, stuffed nose, and sore throat; others, productive coughs with thick mucoid sputum and chest pain, aggravated by coughing. Prostration is alarming, with face flushed, skin hot, extremities mottled, and sweating profuse. There is usually a loss of appetite, nausea, abdominal pain, and constipation, but rarely vomiting and diarrhea. "Intestinal flu" is a misnomer because the influenzal virus does not enter the gastrointestinal tract.

Complications of influenza include secondary bacterial infections of the nasal sinuses, middle ear, bronchi, and lungs. There is a marked rise in the incidence of bacterial pneumonia during influenzal epidemics, especially staphylococcal pneumonia, which runs a fulminant, often fatal course. Recovery from uncomplicated influenza is complete within two to three days or possibly a week, but convalescence is complicated by fatigue, asthenia, and depression, especially in the elderly, who show minor relapses with mild fever.

Prevention and Therapy.—A formalized egg vaccine of the A and B viruses protects 70 per cent of the vaccinated, provided a strain closely related to the strains responsible for the epidemic is present in the vaccine. The vaccine is injected in a single 1-cubic centimeter (cc.) dose subcutaneously to adults; in two 0.5-cc. doses (two to four weeks apart) subcutaneously to older children; and in two intradermal 0.1-cc. doses (two weeks apart) to young children, if there is no allergic sensitivity to eggs or egg products. The reaction rate is about 5 per cent in adults, 20 per cent in older children, and very high and hence dangerous in young children. In 1944 in the United States, 7.1 per cent of the unvaccinated developed influenza in comparison with 2.2 per cent of the vaccinated, while the efficacy of the 1958 vaccine, containing the A' virus attenuates, was about 70 per cent.

Immunization lasts from six months to a year; hence the need for revaccination each fall with a vaccine containing the new antigenic variant of the virus. Influenzal prophylaxis reduces the incidence of infection during epidemics in closed population groups such as schools and camps, but not in the population as a whole. There are several limitations: an attack may occur in spite of the high levels of serum antibody; vaccines are prepared from viruses that differ antigenically from the most recent strains; antibody concen-

tration is low at the site of infection in the respiratory tract; and the protective effect lasts but several months. Public health workers remain on the alert for an impending epidemic, planning preventive and emergency services through a network of World Health Organization reference laboratories.

Specific therapy is neither available nor necessary, for influenza is usually self-limited. Aspirin or APC tablets (aspirin, phenacetin, and caffeine) are offered every four hours. Fluid intake is encouraged to compensate for electrolytes lost in excessive perspiration. A soft diet is offered according to taste. Antibiotics neither affect the course of uncomplicated influenza nor prevent complications. Bed rest is necessary during the febrile course of the illness, but bathroom privileges are permissible. Activity is encouraged after the temperature returns to normal, but fatigue should be avoided. Asthenia during convalescence requires more gradual ambulation until full recovery is attained. There is no evidence that vitamins, iron, tonics, and other body-building remedies are of any value in accelerating recovery.

Consultant to the Departments of Health and Hospitals, New York City.

INFORMATION, in-för-mă'shūn, a proceeding for some offense, usually against the government, differing from an indictment in not being found by a grand jury. It is usually brought by an authorized public official and is in use in the United States and Great Britain. The use of information in the United States is restricted to misdemeanors in criminal cases, but it is allowed in certain civil cases, as to bring a person who has assumed the duties of a civil office into court to show by what authority he so acts or to arraign a corporation for failing to observe the provision of its charter. In England information in criminal cases is brought by the attorney general or solicitor general, but not for treason, misprision of treason, or felonies; however, it is rarely used there except for aggravated offenses, such as sedition, or crimes that are pernicious, such as attempting to bribe public officials. In the United States, in some jurisdictions, violations or attempted violations of the revenue laws are proceeded upon by information. The term is also applied to the written sworn statement made, as before a committing magistrate, prior to the issuance of a summons or complaint. See also INDICTMENT.

INFORMER, in-fôr'mēr, a person who sues for a penalty against those who have infringed any law or penal statute. To encourage the apprehending of certain felons, guilty of offenses not so much criminal as bordering on criminality, many English statutes, from 1692 onward, granted rewards to such as should prosecute to conviction. The fine or penalty in whole or in part inflicted

in the case of a successful conviction and immunity from certain troublesome parish offices were the inducement extended to informers. In many cases resort to this practice has been made in modern statutes. But the institution of a crown prosecutor in Great Britain and of prosecuting attorneys in the United States has nullified the importance of informers to a great extent. One who provides evidence or sues solely to obtain a share of the money penalty assessed is known as a common informer.

INFRARED RADIATION, in-frā-réd' rā-dī-ā'shūn, in physics and optics, that portion of the electromagnetic spectrum which extends from the limit of deep red visible light at about 7,800 angstroms to the microwave region of radio waves at about 1,500,000 angstroms in wavelength. (An angstrom is a unit of length equal to approximately one two-hundred-fifty-millionth of an inch.) Such waves vibrate from 400 trillion times a second (near the visible red portion of the spectrum) to 800 billion times a second (near the microwave end).

Infrared radiation is another name for radiant heat—heat that radiates from a source such as the sun, an electric light bulb, or a candle flame. It is not necessary that the source emit visible light. An electric iron, for example, does not become even red-hot, yet it is a producer of abundant infrared. In fact, any object, such as an ordinary home radiator (steam or hot water), which is warmer than the air around it, radiates heat energy or infrared radiation.

In the electromagnetic or radiant energy spectrum, which includes radio waves, visible light waves, ultraviolet, X-rays and others, the infrared region occurs adjacent to the red end of the light spectrum, which we see as a rainbow of colors, and extends to the region of very short radio waves (microwaves). Hence the prefix *infra*, meaning "below" the red. It is, in effect, "light" having wavelengths too long for our eyes to see. Our sense of touch, however, captures these wavelengths for us and our brain interprets and tells us that "this is hot."

Almost all the practical and common uses of infrared energy utilize the shorter wavelengths from 7,800 to about 40,000 or 50,000 angstroms. This band of waves is called "near" infrared. Uses for "far" infrared radiation between 50,000 and 1,500,000 angstroms are considerably more limited, although these waves exhibit characteristics which provide an intriguing field for further exploration and research in medicine.

Sources and Control of Infrared.—Near infrared energy for commercial and industrial use usually is produced by incandescent lamps so designed that some of their visible light output is sacrificed so that infrared radiation may be produced with greater efficiency. Another efficient method utilizes gas-fired infrared units called "gas radiants." Like other wavelengths of electromagnetic radiation, infrared waves travel through space at the 186,000-mile-per-second speed until they strike a surface where they are absorbed. Most nonreflective substances will absorb and convert into heat a large percentage of the radiant infrared energy striking them, whereas reflecting surfaces redirect and control it, just as visible light waves are reflected and controlled.

Industrial Applications.—Aside from providing heat to make us comfortable, infrared is put to work in many industrial processes. These

include paint and enamel drying, baking, pre-heating, and dehydrating.

Basically these processes are the same. Banks of incandescent infrared lamps are used, each lamp being equipped with its own reflector. The reflector can be applied as an "aluminized" surface to the glass bulb itself or as a separate element in back of a lamp. Gold-plated steel reflectors, while not as efficient as other surfaces for visible light, reflect the greatest amounts of useful infrared and are used extensively in industry. Such reflectors control the infrared rays, just as do those used for visible light. An opaque object placed in the "beam" of radiant heat will cast an invisible "shadow" by absorbing the radiations that strike it.

The one pronounced advantage of using radiant infrared energy for drying paints, lacquers, and similar finishes or for dehydrating and baking materials is the reduction of time involved to accomplish the task. Near infrared radiation is penetrating, that is, the heat is absorbed *within* the object being treated, so that a film of paint tends to dry from the inside out rather than from the surface inward, as with oven drying or baking. Processes that formerly required as much as 15 to 20 hours normal drying time are frequently completed with infrared in a matter of 15 or 20 minutes. Others may require no more than one or two minutes, as compared with over an hour for oven drying.

Different materials, such as iron and wood, have different heat-conducting characteristics, and the types of finishes to be dried or baked vary widely in their composition, so that more time will be required for some than for others. The color of a finish also affects its drying time. Light finishes usually take longer to dry thoroughly, because some of the infrared will be reflected, whereas darker paints or lacquers dry more rapidly by virtue of more rapid infrared absorption. The same time differences occur in dehydrating operations. A hard, wet surface of metal can be dried more quickly, for example, than a wet rug or a water-soaked piece of wood, but in either case the drying time would be less than with heated air as the only drying medium.

Radiant heat requires no air for its transmission. The air present between an infrared source and the object is heated only to a comparatively negligible extent. Thus with infrared radiant drying it is not always necessary to exclude circulation of air or to provide insulation to confine the heat. Some ovens are enclosed, however, in order to heat the air and, therefore, to aid the drying action, while others may be left open to allow the escape of fumes and smoke resulting from paint drying.

Infrared Therapy.—Infrared radiation also serves in the field of medicine. The sun, producing more than an abundance of infrared, has been considered and recognized as a great healing agency since the dawn of civilization. The same radiations as those of the sun, produced artificially in therapeutic lamps, have the characteristic warming effect, so that heat is generated in the body tissue directly beneath the skin and is transmitted deeper by conduction. Bruised and strained muscles and ligaments can be relaxed and soothed with a consequent decrease in pain by infrared application.

Infrared Photography.—The use of infrared radiation in photography has made it possible to extend that art beyond the limits of normal

vision. Objects can be photographed in absolute darkness or through a haze which makes them visually obscure.

We see an object by virtue of the visible light which it reflects. Most objects reflect infrared as well as light, but infrared is beyond the limit of the eye's sensitivity. A camera, however, equipped with film sensitized to infrared radiation by means of special emulsions will capture objects or landscapes which the eye cannot see. Thus, an object in the kitchen can be photographed at night and without light, merely by heat from a stove which is not even red-hot. Since infrared possesses far greater penetrating power than visible light and since all objects reflect infrared, it is possible to photograph landscapes through a haze so thick that they cannot be seen. After considerable research work, film which is sensitive to infrared radiation as long as 12,000 angstroms in wavelength has been developed. If this film is used in the daytime, special lens filters, which are opaque to visible light but not to infrared, must be placed over the lens. Black and white photographic prints from an infrared film have a somewhat unusual reversed appearance due to reflection factors of objects which are different for infrared than for visible light. A blue sky or lake, for instance, will appear quite dark, whereas red, green, or yellow objects will appear much lighter than in a regular photograph.

Conversion of Infrared to Visible Light.—Since infrared radiation is invisible, but behaves much like visible light, that is, can be reflected and controlled in a beam pattern, it has served as a means of communication for specific wartime applications. Signaling in code with infrared radiators was accomplished during World War II, and the development of equipment which would receive the invisible signals and convert them into visible light was the foundation for the design and successful use of some highly important weapons.

An infrared rifle, sometimes referred to as the "sniperscope," was used most effectively. It is equipped with an infrared source and reflector which focuses a rather concentrated invisible beam for some distance in the direction of aim. In this way, an area in the line of sight is "spotted" with invisible radiation and reflects this radiation toward the rifleman. The reflected energy from the target is received and converted electronically into a visible scene that only the rifleman can see.

The conversion of infrared energy into visible-light energy is comparatively simple in the signaling operations, since it is only necessary to perceive a "flash" or impulse. This is accomplished, basically, with an infrared sensitive cell or phosphor button which is excited by the invisible signal and reradiates it as a visible flash of light at the receiving end.

Infrared Cooking.—Although all food cooking utilizes infrared at the source of heat, those appliances which use it directly rather than through pots, pans, and other utensils, are rather often referred to as "infrared cookers." These are such appliances as broilers and toasters, wherein the food is exposed directly to the infrared radiation.

Discovery and History.—The existence of the infrared region was discovered by Sir William Herschel, an English astronomer of German origin, who was the first to think that heat was

distributed unequally in the solar spectrum. Using a prism, he found, in 1880, that a thermometer placed beyond the red end of the spectrum recorded a higher temperature than one in the areas of visible light. James Clerk Maxwell, the Scottish physicist, formulated the electromagnetic theory of light in a series of papers published in 1864 and 1873, and suggested that there might be other waves longer even than the infrared. An American, Samuel P. Langley, who carried on important investigations in this area, invented the bolometer (q.v.) in 1878 to obtain more precise measurements. The English chemist and physicist, Sir William Abney, was apparently the first to make use of infrared in photography about 1880. In 1901, the German physicist, Max Planck, introduced his theory that energy transfers in radiation occur in distinct increments of energy called "quanta," and this has led to the development of modern quantum mechanics. See also HEAT TRANSFER; LIGHT; QUANTUM THEORY; SPECTROSCOPY.

DON P. CAVERLY,

Author, "A Primer of Radiant Energy."

INFRINGEMENT, in-frinj'měnt, in law, means the wrongful invasion of some legal right. The term has no technical meaning except when associated with other words, as, for example, in the phrase "infringement of a patent." Thus the word *infringement* may be applied to the breach of a contract, the violation of a corporation's right to the exclusive use of its name, or the invasion of a ferry franchise by a competing ferry or bridge. Ordinarily, however, infringement refers specifically to patents, copyrights, trademarks, or trade names, and the term has various technical definitions depending upon the particular phrase in which it is used.

Infringement of a patent is the unauthorized making, selling, or using a device which accomplishes substantially the same result as a patented object by substantially identical means and method of operation. The unauthorized manufacture, sale, or use must take place within the area and the time covered by the patent. A close copy constitutes an infringement, even though there are changes in form or position of the operative parts of an apparatus. Infringement cannot be avoided by a multiplication of the elements and parts of a patented invention or by a separation of one integral part into two. Merely obtaining the same result is not an infringement, if substantially the same means and methods are not used. In the case of a design patent, the test of infringement is substantial similarity which might deceive the ordinary purchaser.

Infringement of a trademark or trade name consists of the unauthorized use of a closely similar, but not necessarily identical, mark or name. As in the case of a patent design, the test is whether an average purchaser buying with ordinary care would probably be deceived by the similarity of the mark or name.

Infringement of a copyright is the copying of a substantial portion of copyrighted material. As in the case of patents, the term applies only to acts done within the territorial and temporal limits of the copyright. Material which may be the subject of copyright infringement includes literary works, musical compositions, works of art, maps and charts, photographs, and motion pictures. See also PATENTS, THE LAW OF; TRADE-MARKS.

RICHARD L. HIRSHBERG.

INFUSORIA, in-fû-sô'ri-à, a group of microscopic organisms, especially Protozoa. Originating about 1760, the term has had various meanings since that time, but dropped from use in the 1930's. Originally it included all the microscopic organisms which appear in infusions of dead animal or vegetable materials. Later it was restricted to those organisms which are now placed in the phylum Protozoa; still later, to those protozoans now in the class Ciliata.

INFUSORIAL EARTH, in-fû-sô'ri-ăl ūrth, is earth composed of or containing the remains of infusorians; the term is often incorrectly applied to diatomaceous earth.

INGALLS, ing'gälz, **James Monroe**, American soldier: b. Sutton, Vt., Jan. 25, 1837; d. Stamford, Conn., May 1, 1927. He served in the Civil War as an enlisted soldier and remained in the South until 1871 during reconstruction. In 1882 he founded the Department of Ballistics at the United States Artillery School, Fort Monroe, Va., and was the principal instructor there until the school suspended operations in April 1898, on the outbreak of the war with Spain. He wrote extensively in the field of ballistics, among his works being the volumes *Ballistic Machines* (1885); *Exterior Ballistics* (1883; 2d ed., 1886); *Ballistics for the Instruction of Artillery Gunners* (1893); *Ballistic Tables* (1891; rev. ed., 1917); and *Interior Ballistics* (1894; 3d ed., 1912).

INGALLS, John James, American politician: b. Middleton, Mass., Dec. 29, 1833; d. Las Vegas, N.Mex., Aug. 16, 1900. After graduating from Williams College in 1855, he was admitted to the Massachusetts bar in 1857 and in 1858 moved to Kansas, where he established a law practice first in Sumner and then, in 1860, in Atchison. Ingalls was a delegate to the first constitutional convention, the Wyandotte Convention, in Kansas in 1859, and served as secretary of the territorial council (1860) and of the state Senate (1861). He was elected a member of the state Senate in 1862. He acted as judge advocate of the Kansas militia during the Civil War and later edited the *Atchison Freedom's Champion*.

In January 1873 the Kansas legislature sent Ingalls to Washington, D.C., as senator, an office to which he was subsequently re-elected in 1878 and 1884. Charges that bribery had been practiced in connection with his election in 1878 were made in and investigated by both the Kansas House of Representatives and the United States Senate, but Senator Ingalls was exonerated and he retained his Senate seat. From 1887 to 1891 he was president pro tempore of the Senate. During his terms in the Senate he became well known for his oratory, especially for his vitriolic attack and abuse; he constantly waved the "bloody shirt" and appealed to sectional hatreds. Again a Republican candidate for the Senate in 1890, Ingalls was defeated by the Populist Party candidate. His writings were edited by William E. Connelley as *A Collection of the Writings of John James Ingalls* (Kansas City 1902).

INGALLS, Melville Ezra, American railroad executive: b. Harrison, Me., Sept. 6, 1842; d. Hot Springs, Va., July 11, 1914. He studied at Bowdoin College and was graduated from the Harvard Law School in 1863. Subsequently he practiced law successively at Gray, Me., and Bos-

ton, Mass. He specialized in corporation law, particularly as it affects transportation, and in 1870 became president of the Indianapolis, Cincinnati & Lafayette Railroad. By 1880 he had twice reorganized the company, consolidating it with another line to form the Cincinnati, Indianapolis, St. Louis & Chicago Railway, of which he was named president. Finally, in 1889 he consolidated his line with the Bee Line of the Vanderbilt interests, forming the Cleveland, Cincinnati, Chicago & St. Louis Railway Company, which he served as president until 1905. Ingalls was also president of the Kentucky Central Railroad (1881–1883) and the Chesapeake & Ohio Railway Company (1888–1900). Vigorous, affable, and a determined opponent of all government regulation, he was typical of the pioneer railroad builders in the United States.

INGE, inzh, **William (Motter)**, American playwright: b. Independence, Kans., May 3, 1913. With four successive hit plays on Broadway during the 1950's, he ranked as one of the foremost playwrights of the contemporary American theater. The critic George Jean Nathan hailed his "faithful observance of life, sharp appreciation of character and gift for beautifully accurate dialogue."

Inge's childhood ambition was to be an actor, and he performed in high school, college, and stock company productions. After majoring in drama at the University of Kansas (B.A., 1935), he abandoned the idea of an acting career to become a teacher. He taught first in a high school and then at Stephens College, Columbia, Mo. Next, he served for three years as drama critic for the *St. Louis Star-Times*. While teaching English in 1947 at Washington University, St. Louis, he wrote his first play, *Farther Off from Heaven*.

At the age of 37, Inge achieved his first stage success with *Come Back, Little Sheba* (1950), which starred Shirley Booth. He followed this with *Picnic* (1953), *Bus Stop* (1955), and *The Dark at the Top of the Stairs* (1957). All of these enjoyed long runs on Broadway and were made into motion pictures. *Picnic*, the story of a handsome wastrel's one-day visit to a small Kansas town, received the Pulitzer Prize and the New York Drama Critics' Circle Award. Two of Inge's later efforts—*A Loss of Roses* (1959) and *Natural Affection* (1963)—drew unfavorable reviews and closed after brief engagements. Between those failures, he moved to Hollywood, where he wrote the script for the film *Splendor in the Grass*. This movie won an Academy Award for the best original screenplay of 1961.

INGE, ing, **William Ralph**, English clergyman and author: b. Crayke, Yorkshire, England, June 6, 1860; d. Wallingford, Berkshire, Feb. 26, 1954. The son of William Inge, provost of Worcester College, Oxford, he was educated at Eton College and at King's College, Cambridge, where he made a brilliant record. He then served as assistant master of Eton, 1884–1888, and from 1886 to 1888 he was, as well, a fellow of King's College; from 1889 to 1904 he was a fellow and tutor of Hertford College, Oxford. Subsequently he served as vicar of All Saints', Ennismore Gardens, London, 1905–1907; became Lady Margaret professor of divinity and a fellow of Jesus College, Cambridge, 1907–1911; and in 1911 was appointed 91st dean of St. Paul's Cathedral, Lon-

don, a post he continued to occupy until 1934.

Through his lectures, sermons, and writings, expressing a frequently nonconformist view of both religious and secular topics, Inge became a nationally known figure, and his views were widely sought. Critically outspoken and a consistent foe of cant and hypocrisy, he so pessimistically regretted the course of modern times that he came to be called "the gloomy dean." Inge also took a great interest in mysticism and investigated extensively the relations between Christianity and Greek philosophy.

Among his numerous books are the following: *Christian Mysticism* (1899); *Studies of English Mystics* (1906); *The Philosophy of Plotinus* (1918); *The Platonic Tradition* (1926); *The Church in the World* (1927); *Christian Ethics and Modern Problems* (1930); *Our Present Discontents* (1938); and *Mysticism in Religion* (1947).

INGEBORG, ĕng'ĕ-börg (Fr. INGEBURGE, ān-zhĕ-bŭrzh', or INGELBURGE, ān-zhĕl-bŭrzh'), queen of France: b. Denmark, c. 1176, d. Corbeil, France, July 21, 1236. Daughter of King Valdemar I the Great of Denmark and sister of King Canute VI of Denmark, she was married on Aug. 14, 1193, to King Philip II Augustus of France, who on the day following the marriage took an intense dislike to her, despite her youth and beauty, and attempted to have the marriage annulled. He imprisoned Ingeborg in the convent of Cysoing, in the diocese of Tournai. A council of barons and clergy at Compiègne (1193) pronounced an annulment of the marriage, but Popes Celestine III and Innocent III took the part of Ingeborg, and, when Philip married Agnes of Meran in 1196, he was excommunicated and his kingdom was put under an interdict. Having need of the pope's aid, Philip made a pretense of submitting before the Council of Soissons in 1201, but still did not free Ingeborg. Eventually, in 1213, the king was reconciled to Ingeborg, whom he released from the castle of Étampes, to which she had been confined for the preceding 12 years, and restored her rights. After the death of Philip in 1223, Ingeborg lived in retreat at the priory of St. Jean at Corbeil.

INGELOW, in'jĕ-lō, **Jean**, English poet and novelist: b. Boston, Lincolnshire, England, March 17, 1820; d. London, July 20, 1897. Her first work, *A Rhyming Chronicle of Incidents and Feelings*, appeared anonymously in 1850 and, like her later poetry, included recollections of her childhood in Lincolnshire. Not until the publication of her *Poems* in 1863 did she attract much public attention; but this volume won enthusiastic critical praise and public approval and by 1879 it had passed through 23 editions. The best-known poems in this volume were *High Tide on the Coast of Lincolnshire, 1571*, *Divided*, and *Supper at the Mill*. She published further poems in *A Story of Doom* (1867); *Monitions of the Unseen* (1871); *The Shepherd Lady and Other Poems* (1876); and *Poems of the Old Days and the New* (1885). The influence of William Wordsworth and Alfred, Lord Tennyson, is marked in her poetry, which is characterized by acute observations of nature and a deep sympathy for common life. She was hailed in the 19th century for her lyric gifts, and several of her poems were set to music.

She also wrote many children's stories, usually under the pen name "Orris." Among them are *Studies for Stories* (1864); *Stories Told to a Child* (1865); *A Sister's Bye-Hours* (1868); and

Mopsa, the Fairy (1869). Her novels, once popular, are no longer read; they include *Off the Skelligs* (4 vols., 1872); *Fated to be Free* (3 vols., 1875); *Sarah de Berenger* (3 vols., 1879); *Don John: A Story* (3 vols., 1881); and *John Jerome* (1886).

INGEMANN, ɛŋ'ĕ-măn, **Bernhard Severin**, Danish poet and novelist: b. Torkildstrup, Falster, Denmark, May 28, 1789; d. Sorø, Zealand, Feb. 24, 1862. While still a student at the University of Copenhagen, he published his first poems, which were of a dreamy, melancholy nature and were filled with a sickly mysticism, showing markedly the influence of German romanticism. He subsequently published a long allegorical poem and several plays, of which *Blanca* (1815), a tragedy, was the most popular.

In 1822, Ingemann accepted the chair of Danish language and literature at the Academy of Sorø. Inspired by the success of Sir Walter Scott in his Waverley novels and anxious to rouse his country to renewed national pride after the defeats of the Napoleonic Wars and the loss of Norway, he turned to the historical novel, taking his subjects and characters from Danish history. Although his historical romances were frequently inaccurate in detail, they were written with such verve and had such a national flavor that they became very popular. Among these historical romances were the following: *Valdemar Seier* (1826; Eng. tr., *Waldemar, Surnamed Seir, or the Victorious*, 1841); *Erik Menveds Barndom* (1828; Eng. tr., *The Childhood of King Erik Menved*, 1846); *Kong Erik og de Fredløse* (1833; Eng. tr., *King Erik and the Outlaws*, 1843); *Prinds Otto af Danmark* (1835; *Prince Otto of Denmark*); Achieving great popularity, too, were the religious poems of pious innocence in *Morgen og Aftensange* (1839; *Morning and Afternoon Songs*) and the earlier epic poem *Valdemar den Store og hans Moend* (1824; *Waldemar the Great and His Men*). His collected works in 41 volumes were published in Copenhagen (1843-65).

INGENHOUSZ, ɪŋ'ĕn-hous, **Jan**, Dutch physician and scientist: b. Breda, the Netherlands, Dec. 8, 1730; d. Bowood, near Chippenham, Wiltshire, England, Sept. 7, 1799. Educated in medicine at Louvain, he also studied subsequently at the universities of Leiden, Paris, and Edinburgh. After practicing in the Netherlands for six years, he went to London in 1764 or 1765, where he utilized extensively the new discovery of smallpox inoculations. Going to Vienna to inoculate members of the Austrian imperial family, Ingenhousz was rewarded in 1769 with a lifetime pension and was made aulic counselor and body physician to Emperor Joseph II and Maria Theresa.

In 1779 he returned to London and was elected a fellow of the Royal Society, having already contributed several treatises to its *Philosophical Transactions*. In addition to his papers contributed to the Royal Society, which were concerned with electricity and magnetism and atmospheric gases, Ingenhousz wrote the important *Experiments on Vegetables, discovering their great Power of purifying the common Air in Sunshine, but injuring it in the Shade or at Night* (1779), which contained the discovery of the carbon dioxide-oxygen respiration cycle of plants. A collection of his scientific papers was published as *Nouvelles expériences et observations sur divers objets de physique* (2 vols., 1785-89).

INGENIEROS, ɛn-hă-nyă'rôs, **José**, Argentinian psychiatrist, sociologist, and philosopher: b. Buenos Aires, Argentina, April 24, 1877; d. there, Nov. 1, 1925. After receiving his medical degree in 1900 from the University of Buenos Aires, he specialized in the study of problems of nervous and mental pathology. He became director of the psychopathic wards of the hospitals of Buenos Aires in 1901 and was named professor of experimental psychology in the Faculty of Medicine of the University of Buenos Aires in 1904. His clinical work soon led him to the study of criminal anthropology and to oppose the widely accepted views of the Italian criminologist Cesare Lombroso. In 1907, Ingenieros founded the Buenos Aires Institute of Criminology. His later interests were primarily in the field of the history of philosophy, in which he was a disciple of Auguste Comte and Herbert Spencer, and he became one of the leaders of positivist thought in Latin America. Ingenieros served as editorial director of *Archivos de psiquiatria y criminologia* from 1902 to 1913 and of *Revista de filosofia* from 1915 until his death. Among his outstanding works are the following: *La psicopatologia en el arte* (1902); *La simulación de la locura* (1903); *El hombre mediocre* (1913); *Principios de psicología biológica* (1913); and *La evolución de las ideas argentinas* (2 vols., 1918-20).

INGENU, L', lăn-zhă-nü', a satirical romance by Voltaire, was published first in 1767. *L'ingénu* tells the story of Hercule de Kerkabon, who comes with all the virtues of uncorrupted nature from the land of the Hurons to Europe, where he runs afoul of the prejudices and customs, as well as the vices, of civilized society. Finally he learns that he must take the world as it is.

INGERMANNLAND, ɪŋ'ĕr-măn-lănd, or **INGRIA**, ɪŋ'ĕr-ă (Russ. INGRĬYA), ancient district of the Soviet Union, is located between Lake Ladoga and Lake Peipus in Leningrad Oblast, Russian Soviet Federated Socialist Republic. At one time part of the principality of Novgorod, the region was long in dispute between Sweden and Russia. It was taken by Gustavus II Adolphus of Sweden in 1617 and was occupied in 1703 by Peter I the Great of Russia, who in 1708 created a *guberniya*, or administrative district, of this name (renamed St. Petersburg in 1710). Ingermanland, which includes the present city of Leningrad, was annexed permanently to Russia by the Treaty of Nystad in 1721.

INGERSOLL, ɪŋ'ĕr-sŏl, **Charles Jared**, American lawyer and statesman: b. Philadelphia, Pa., Oct. 3, 1782; d. there, May 14, 1862. Growing up in Philadelphia during the early years of the young republic and having before him the examples of public service of his father and grandfather, both named Jared Ingersoll (qq.v.), he moved quite naturally toward a legal and political career. He left Princeton College in 1799 before completing his courses, and turned to the study of law and the writing of verse and drama. His tragedy, *Edwy and Elgiva*, was produced in Philadelphia in 1801.

Ingersoll's early travel in Europe probably helped to change the Federalist views wherein he had been nurtured, for in his first book, written after his return, *A View of the Rights and Wrongs, Power and Policy, of the United States*

of America (1808), he took an anti-Federalist and anti-British approach to foreign relations. In 1810 he followed this book with *Inchiquin, the Jesuit's Letters*, which attacked the comments of British travelers on the United States and helped to arouse a feeling of national self-sufficiency.

Leaving Congress, in which he had served one term (1813-1815) as a Jeffersonian Republican, Ingersoll became United States district attorney for Pennsylvania, an office which he held from 1815 to 1829, and in 1830-1831 a Pennsylvania state assemblyman. His paper on "The Influence of America on the Mind," given before the American Philosophical Society in 1823, was widely read at home and abroad. He published, also, *Julian: A Tragedy* in 1831. During the dispute for renewal of the charter of the Second Bank of the United States, Ingersoll approved President Andrew Jackson's course and helped to draft the subtreasury plan. He also favored limitations on corporation powers and opposed the interpretation of charters as irrevocable contracts, which was so decided in 1819 by the Supreme Court in the celebrated Dartmouth College Case (q.v.).

Ingersoll was nominated for Congress by the Jacksonian Democrats of Pennsylvania in 1837 and 1838, but failed to gain election; however, in 1840, he was elected and continued in the House of Representatives until 1849. In the House he held the important post of chairman of the Foreign Affairs Committee and played a prominent part in the annexation of Texas. He opposed the extreme Northern antislavery view, took a leading role in the debates on the sectional controversies, and frequently espoused causes unpopular among his own social group. He also wrote a significant history of the War of 1812, which appeared in four volumes under two titles: *Historical Sketch of the Second War Between the United States of America and Great Britain* (2 vols., 1845-49) and *History of the Second War Between the United States of America and Great Britain* (2 vols., 1852); and his *Recollections* (2 vols., 1861).

INGERSOLL, Jared, American public official: b. Milford, Conn., 1722; d. New Haven, Conn., Aug. 25, 1781. Upon graduating from Yale College in 1742, he studied law and soon established a legal practice in New Haven, becoming very successful in his profession. In 1751 he was named king's attorney for the county of New Haven. From 1758 to 1761 and again in 1764 he served as London agent for the colony. Though he was at first opposed to the proposals for a stamp tax on the colonies, Ingersoll soon came to feel that such a measure was justified and worked to make it as little objectionable as possible to the American colonists. After passage of the Stamp Act (1765), Prime Minister George Grenville appointed Ingersoll stamp master for Connecticut, Ingersoll accepting on the advice of Benjamin Franklin. But the colonists were aroused, riots and burnings ensued, and, like most of the other stamp agents, Ingersoll was forced by mob action to resign his post. He subsequently retired to the position of justice of the peace in New Haven and continued his law practice. In 1768 he was appointed judge of a court of vice admiralty with its seat at Philadelphia, where he lived from 1771 until 1777, when on the approach of Lieut. Gen. Sir William Howe he was, as a Loyalist, forced by the American Patriots to leave and to return on parole to New Haven. There he spent the remainder of his life.

INGERSOLL, Jared, American lawyer: b. New Haven, Conn., Oct. 27, 1749; d. Philadelphia, Pa., Oct. 31, 1822. A few years after graduation from Yale College in 1766, he moved to Philadelphia, where his father Jared Ingersoll (q.v.) was a judge in the vice admiralty courts, to pursue the study of law, which he continued after July 1773 at the Middle Temple in London. During his stay in England he renounced his father's Loyalist views and espoused the cause of the colonies. Returning to Philadelphia, after about three years in England and nearly two years on the Continent, Ingersoll quickly won for himself a position as a leading lawyer. In 1791 he was admitted to practice before the Supreme Court of the United States.

In the meantime Ingersoll held various public offices. In 1780-1781 he served in the Continental Congress and in 1787 he represented Pennsylvania at the Constitutional Convention. He was also attorney general of Pennsylvania from 1790 to 1799 and from 1811 to 1817, city solicitor of Philadelphia from 1798 to 1801, and United States district attorney for Pennsylvania in 1800-1801. The Federalist Party in 1812 nominated Ingersoll for the vice presidency of the United States on a ticket headed by DeWitt Clinton, but the Federalist's candidates were defeated by their Republican opponents, James Madison and Elbridge Gerry. From March 1821 until his death he presided over the district court of the city and county of Philadelphia.

INGERSOLL, Robert Green, American lawyer, lecturer, and author: b. Dresden, N.Y., Aug. 11, 1833; d. Dobbs Ferry, N.Y., July 21, 1899. The son of an orthodox Congregational minister, he was educated in various towns in Ohio, Wisconsin, and Illinois, where his father preached. He was admitted to the bar in 1854 in Illinois, practicing first at Shawneetown, Ill., and then at Peoria, Ill., and soon became a prominent lawyer and Democrat.

When the Civil War began, Ingersoll recruited the 11th Illinois Volunteer Cavalry Regiment and entered the army as its colonel. He saw action at the battles of Shiloh and Corinth, and on Dec. 18, 1862, he was captured at Lexington, Tenn., by Confederate raiders under Gen. Nathan Bedford Forrest. Soon he was paroled and given command of a camp, but, seeing no possibility of exchange, he resigned from the army in June 1863.

During the war Ingersoll changed his politics from Democratic to Republican. From 1867 to 1869 he served as Republican attorney general of Illinois. He was a delegate to the Republican National Convention of 1876 at Cincinnati, Ohio, where he placed James Gillespie Blaine in nomination for the presidency, terming him "the plumed knight." Ingersoll's nominating speech gave him immediate national recognition and he subsequently became one of the most popular lecturers of the late 19th century in the United States. Although some of his best-known lectures were on such historical personages as Shakespeare, Lincoln, Thomas Paine, Robert Burns, and Voltaire, his most famous lectures concerned more strictly religious subjects; perhaps the most popular were "The Gods" (1872), "Some Mistakes of Moses" (1879), "Why I Am an Agnostic" (1896), "Superstition" (1898), and "The Devil" (1899). In fluent prose, with great dialectic skill, and with seeming "scientific" arguments, he attacked in the tradition of freethinking rationalism what he felt

were the "superstitions" of the Bible and the beliefs of Christianity, earning for himself the epithet "the great agnostic."

Ingersoll was prominent in politics for several years, speaking often at party rallies, and, if he had not given such frequent expression to his agnostic views, he doubtless would have been honored with high offices. He was also a successful trial and corporation lawyer, his most notorious case coming in conjunction with the "star route frauds," in which he gained first a mistrial and later the acquittal (1883) of the leading defendants.

Bibliography.—*The Works of Robert G. Ingersoll*, the complete Dresden edition, was published in 12 volumes (New York 1900; reprinted 1910). His *Letters* were edited by Eva Ingersoll Wakefield (New York 1951). Consult Goldthwaite, Vere, ed., *The Philosophy of Ingersoll* (San Francisco 1906); Kittredge, Herman, E., *Ingersoll: A Biographical Appreciation* (New York 1911); Baker, Isaac, *An Intimate View of Robert G. Ingersoll* (New York 1920); Gorham, Charles T., *Robert G. Ingersoll* (London 1921); Rogers, Cameron, *Colonel Bob Ingersoll* (Garden City, N.Y., 1927); Cohen, Chapman, *Bradlaugh and Ingersoll* (London 1933); Cramer, Clarence H., *Royal Bob* (Indianapolis 1952).

INGERSOLL, Robert Hawley, American merchant and manufacturer: b. Delta, Mich., Dec. 26, 1859; d. Denver, Colo., Sept. 4, 1928. Having only a few years of grammar school education, he worked on his father's farm when a youth and went east when he was 20 years old. In New York City he used his small savings in 1880 to establish himself in the rubber-stamp business; as a side line he produced novelties, such as a toy typewriter and a dollar sewing machine. As his business expanded, he moved into the mail-order and then the chain-store fields. Feeling the need for a single item to stabilize his sales and to serve as a focal point for his manufacturing and sales operations, he introduced in 1892 a cheap watch, supplied by the Waterbury Clock Company; he sold the watch for \$1, eventually under the name "Ingersoll," promoted by the slogan "The Watch That Made the Dollar Famous." By 1919 an estimated 70 million Ingersoll watches had been sold. Three years later the firm went into receivership and was sold to the Waterbury Clock Company, and Ingersoll spent the remaining years of his life promoting a dollar razor strop.

INGERSOLL, Simon, American inventor: b. Stanwich, Conn., March 3, 1818; d. Stamford, Conn., July 24, 1894. Educated in the country schools of his birthplace, he soon became locally recognized for his mechanical ingenuity, though little is known of his early years. His first patent, in 1858, was for a steam engine rotating shaft; he also built in Stamford, Conn., a workable steam wagon. Ingersoll obtained patents on a gate latch, a friction clutch, and a spring scale in the 1860's. Unable, however, to support himself as an inventor, he turned to truck gardening about 1870, in which he had previously engaged, and had a stall in the Fulton Market, New York City. There he was encouraged by a contractor to invent a rock drill, which he succeeded in doing and patenting in 1871, later selling his patent rights to José F. Navarro of New York City. He returned to Stamford and became a partner in a machine shop, where he worked the rest of his life, especially on rock drills and guns. His inventions brought him no great return, and he died nearly destitute.

INGERSOLL, town, Ontario, Canada, located in Oxford County, on the Thames River, 18

miles east of London. It is the center of a mixed farming district well known for its dairy products. The industrial establishments of the town include furniture and hardware plants and flour mills. Fertilizers and lumber products are also made. Ingersoll is served by the Canadian National and Canadian Pacific railways and is situated at the junction of two highways. It is named for Maj. Thomas Ingersoll, who settled here from Massachusetts in 1793. Laura Secord (q.v.), heroine of an episode in the War of 1812, was Ingersoll's daughter. Pop. 6,874.

INGHAM, ing'am, Benjamin, English evangelist: b. Ossett, Yorkshire, England, June 11, 1712; d. Aberford, Yorkshire, 1772. He received his education at Batley School and at Queen's College, Oxford, from which he was graduated in 1734. In 1735 he was ordained, and, becoming associated with John and Charles Wesley, went with them to Georgia, remaining 13 months. In 1738 he went with John Wesley on a visit to the Moravians in Germany and became so strongly attached to their doctrines that he broke with the Wesleys and founded in Yorkshire several congregations of what were known as "Moravian Methodists," but more commonly as "Inghamites." He endeavored to unite in this organization the chief doctrines of the Moravians and Methodists, and so successful was he as bishop or general overseer that in a few years there were about 80 of these congregations in England. In 1754 he broke his ties with the Moravians, and his congregations became practically independent. After he had adopted some of the mystical views of Robert Sandeman in 1760, the greater part of his followers deserted him. Only about 13 of the Inghamite churches followed him into the Sandemanian sect; the rest were absorbed by other sects, especially the Methodists. Ingham wrote *A Discourse on the Faith and Hope of the Gospel* (1763).

INGHAM, Charles Cromwell, American painter: b. Dublin, Ireland, 1796; d. New York, N.Y., Dec. 10, 1863. After a short period of study at the Royal Dublin Society, he studied for some years with William Cuming, a Dublin portraitist. While still a student he painted a *Death of Cleopatra*, which he later exhibited, to general acclaim, at the American Academy of Fine Arts, New York City. Ingham came to the United States in 1816, settling in New York City, and devoted himself to portraits and miniatures, especially of women and children. He also painted certain prominent public figures, including Governor DeWitt Clinton and the marquis de Lafayette (both portraits in the New York Historical Society collection). In 1826 he helped to found the National Academy of Design and subsequently served as its vice president. Among his other paintings is *The Flower Girl* (1846), in The Metropolitan Museum of Art, New York City.

INGLE, ing'g'l, Richard, English sea captain: b. in England, 1609; d. probably in Maryland, after 1653. When the English Civil War began, Ingle was engaged in the Maryland tobacco trade. He espoused the parliamentary cause and in 1644, together with William Claiborne, expelled Governor Leonard Calvert from Maryland. The latter, however, gathered forces from Virginia and repossessed Maryland in 1646. During his rule Ingle committed numerous outrages against the Marylanders. Charges were made against him in Eng-

land, where he defended himself on the ground that he had acted from religious motives and had plundered only "papists." When the proprietary government was restored in 1646, Ingle was not included in the general amnesty granted to the other rebels. On Nov. 14, 1653, he petitioned for a share of prize money, and thereafter disappears from history.

Consult Ingle, Edward, *Capt. Richard Ingle, the Maryland Pirate and Rebel, 1642-1653* (Baltimore 1884).

INGLEBY, ینگ'g'l-bī, Clement Mansfield, English writer and Shakespearean critic: b. Edgbaston, near Birmingham, Oct. 29, 1823; d. Ilford, Essex, Sept. 26, 1886. He was educated at Trinity College, Cambridge University, receiving his B.A. degree in 1847 and his M.A. in 1850. He practiced law with his father, a well-known Birmingham solicitor, until 1859, when he moved to Ilford, near London, and devoted himself to writing on metaphysical and literary subjects. His best-known works are his Shakespearean studies, among which are *The Shakespeare Fabrication* (1859) and *A Complete View of the Shakespeare Controversy* (1861), both on the literary forgeries of John Payne Collier (q.v.); *Centurie of Prayse* (1874); *The Still Lion* (1874), republished as *Shakespeare Hermeneutics* (1875); *Shakespeare: The Man and the Book* (1877-1881); and an edition of *Cymbeline* (1886). He also wrote *Outlines of Theoretical Logic* (1856) and *Introduction to Metaphysic* (1864-1869).

INGLEFIELD, Sir Edward Augustus, British naval officer and explorer: b. Cheltenham, March 27, 1820; d. London, Sept. 5, 1894. He studied at the Royal Naval College, Portsmouth, from 1832 to 1834, when he went to sea. In 1840 he participated in naval operations off the coast of Syria, and then served in the West Indies. In 1845 he was promoted to the rank of commander. He commanded the yacht *Isabella* on a cruise to Smith Sound in 1852 in search of Sir John Franklin (q.v.). On his return to England, he published an account of this cruise, *A Summer Search for Sir John Franklin* (1853), and was made a fellow of the Royal Society and awarded the gold medal of the Royal Geographical Society. As commander of the *Phoenix*, he made two more trips to the Arctic: one in 1853 to relieve Sir Edward Belcher, and one in 1854 in which he rescued part of the Belcher expedition and made a last attempt to find Franklin. He fought in the Black Sea during the Crimean War. In 1869 he was promoted to the rank of rear admiral. He served as second in command in the Mediterranean from 1872 to 1875, when he became a vice admiral. He was commander in chief in the North Atlantic in 1878-1879. He was knighted in 1877, and two years later was promoted to the rank of admiral. He retired in 1888. Inglefield invented the anchor known by his name and the hydraulic steering gear.

INGLEWOOD, city, California, situated in Los Angeles County, at an altitude of 115 feet, 10 miles southwest of downtown Los Angeles, of which it is a residential suburb. It is served by the Atchison, Topeka and Santa Fe and the Pacific Electric railroads; the Los Angeles International Airport is nearby. The city has chin-chilla farms, oil refineries, and plants producing airplanes, machinery, metal products, pottery, plastics, and furniture. Founded in 1873 by

Daniel Freeman, Inglewood was laid out in 1887 and incorporated in 1908. It is governed by a mayor and council. Pop. 63,390.

INGLIS, ینگ'g'iz, Charles, British prelate: b. County Donegal, Ireland, 1734; d. Halifax, Nova Scotia, Feb. 26, 1816. Educated in Ireland, he went to Pennsylvania in 1755 and for three years taught school at Lancaster. In 1758 he went to England, where he was ordained in the Church of England. In 1759 he was assigned to a missionary post in Dover, Del., where he remained until 1765, when he became assistant to the rector of Trinity Church, New York City. He became known for his advocacy of the establishment of an American episcopacy and for his work on behalf of the conversion of the Indians. He received an honorary M.A. degree from King's College (now Columbia University) in 1767, and about three years later became one of its governors. In 1770 he received an honorary M.A. degree from Oxford University, and in 1778 an honorary D.D. A stout Loyalist, he refused to omit from the service at Trinity prayers for the king and the royal family, and after the occupation of New York City by George Washington in 1776, he retired for a time to Flushing, Long Island. Returning to New York City in 1777, he became rector of Trinity. When the British evacuated the city in 1783, he went at first to Halifax, Nova Scotia, and then to England, where, in 1787, he was consecrated bishop of Nova Scotia, the first colonial bishop of the Church of England. He went to the colony soon thereafter, was made a member of its council in 1809, and remained there until his death.

His son, JOHN INGLIS (b. New York City, 1777; d. London, England, Oct. 27, 1850), was also a clergyman. He was educated at King's College, Windsor, Nova Scotia; became a deacon in 1801; and assisted his father until 1816, when he went to England. In 1839 he was consecrated third Anglican bishop of Nova Scotia. Inglis was a benefactor of King's College, and he opposed the Anglican test required as a condition for entrance to that institution.

SIR JOHN EARDLEY WILMOT INGLIS (b. Nova Scotia, Nov. 15, 1814; d. Hamburg, Germany, Sept. 27, 1862), son of the preceding, was a soldier. His entire career was passed in the British 32d Foot Infantry, which he joined in 1833. He served in Canada during the insurrection of 1837, and in the Punjab in 1848-1849. He was in command of his regiment at the outbreak of the Indian Mutiny in 1857. Inglis is celebrated chiefly for his brave defense of Lucknow, whose garrison he commanded from July 2 to Sept. 26, 1857. For his services he was knighted and promoted to major general.

INGOLDSBY LEGENDS, The, a collection of tales, mostly in verse and nearly all humorous, by the Rev. Richard Harris Barham (q.v.), whose pseudonym was Thomas Ingoldsby. They appeared in *Bentley's Miscellany* in 1837-1840, and were collected in book form in 1840, with a second and third series in 1847. The literary sources of the tales are extremely varied, ranging from saints' legends, medieval chronicles, and Kentish traditions to Jean de La Fontaine's *Contes*, Johann Wolfgang von Goethe's *Zauberlehrling*, and Friedrich de La Motte-Fouqué's *Undine*, so that they offer the richest mixture of witchcraft,

ghosts, magic, and demonology, with legal, genealogical, heraldic, ecclesiastical, and gastronomic history and anachronisms. Its careful technique in the details of narrative and description is in the tradition of Laurence Sterne; and its rollicking masculine fun is the peculiarly English fun of a bygone day of roast beef, puddings, and ale, a hierarchical social order, and a gentlemanly acquaintance with the classics. Its defects are the often flippant handling of themes essentially serious; the rarity of its genuine wit or humor—their place being generally occupied by fun and volubility; its employment of digression beyond the point where digression ceases to amuse and begins to bore; and its outworn insularity and prejudices. These penalties it pays for smacking so racily of its time and its land. The book takes the gauge of early Victorian England relaxing over the nuts and wine; yet, all detractions made, does it so perfectly as to make itself the permanent model of its genre.

SAMUEL LEE WOLFF.

INGOLSTADT, ینگول-ستادت, Ger. ینگول-شتادت, city, Germany, situated in Bavaria on the Danube River, 43 miles north of Munich. It is a rail and trade center, with such industries as woodworking, brewing, and the manufacture of textiles, automobiles, and tobacco. First mentioned in the 8th century, it was chartered in 1250 and fortified in 1539. From 1392 to 1447 the city was the residence of the dukes of Ingolstadt. The Herzogsschloss (Ducal Palace), begun c. 1400, now a museum, is one of the best secular creations of Gothic art in Germany. Ingolstadt's walls, distinguished by fine towers and gates, were razed by the French in 1800, but were rebuilt during 1828-1840. Ingolstadt was the seat of a university founded in 1472, but the university was removed to Landshut in 1800 and to Munich in 1826, where it is now located. The city suffered some damage in World War II and was captured by the United States Army in the spring of 1945. Pop. (1950) 40,270.

INGRAHAM, ینگرا-هام, **Duncan Nathaniel**, American naval officer: b. Charleston, S.C., Dec. 6, 1802; d. there, Oct. 16, 1891. He entered the United States Navy as a midshipman at the age of nine and served during the War of 1812 and in the Mexican War. In June 1853, while commanding the sloop of war *St. Louis* in Mediterranean waters, he arrived at Smyrna (now İzmir), Turkey, while Martin Koszta, a Hungarian political refugee, was imprisoned aboard an Austrian ship in the harbor, after the Austrians had seized him in Turkey. Koszta previously had declared in New York City his intention of becoming a United States citizen. Under instruction from the United States chargé d'affaires in Constantinople (now İstanbul), Ingraham secured Koszta's release by threat of force, and his action was upheld subsequently by the United States government. (See also **KOSZTA AFFAIR**.)

On Ingraham's return to the United States he was received with acclaim, was raised to the rank of captain in 1855, and acted for over four years as chief of the Bureau of Ordnance of the Department of the Navy. In 1861 he resigned from the service, entered the Confederate Navy, became its chief of ordnance at Richmond, Va., and then commanded its flotilla along the coast of South Carolina from November 1861 to March

1863, after which he was in charge of the naval station at Charleston until the end of the war, when he retired.

INGRAHAM, **Joseph Holt**, American novelist and clergyman: b. Portland, Me., Jan. 25 or 26, 1809; d. Holly Springs, Miss., Dec. 18, 1860. As a youth he went to sea, later becoming a teacher in Washington, Miss. He began to write a sensational type of fiction, and for some years his prolific pen produced such works as *Lafitte: The Pirate of the Gulf* (2 vols., 1836); *Burton, or The Sieges* (2 vols., 1838); and *Scarlet Feather, or The Young Chief of the Abenagues* (1845). About 1849 he began to study theology and was ordained a priest of the Protestant Episcopal Church in 1852. From 1852 to 1858 he served churches in Mississippi, Alabama, and Tennessee, becoming rector of Christ Church, Holly Springs, Miss., in 1859. During this period he also wrote romances of Biblical times, including *The Prince of the House of David* (1855); *The Pillar of Fire* (1859); and *The Throne of David* (1860). Meanwhile he tried to suppress the earlier works. Ingraham was killed by the accidental discharge of his own gun.

His son, **PRENTISS INGRAHAM** (1843-1904), was a soldier of fortune and writer of dime novels. After serving with the Confederate Army in the Civil War, he saw service in many foreign lands—including Austria, in its war with Prussia (1866), and Cuba, in its first war for independence (1868-1878). These experiences, together with his far-flung travels, formed the basis for his more than 600 novels and other writings. *Buffalo Bill's Tough Tussle* (1895) and more than 200 other stories were based on the career of his friend, William Frederick Cody (q.v.), called "Buffalo Bill." Among his other tales were *Zuleikah: A Story of Crete* (1887); *An American Monte Cristo* (1891); and *The Girl Rough Riders* (1903).

INGRAIN. See **HOSIERY INDUSTRY AND HOSE—Hosiery Terms**.

INGRAM, ینگرام, **Arthur Foley Winington**, English prelate: b. Stanford-on-Teme, Worcestershire, England, Jan. 26, 1858; d. Upton-on-Severn, Worcestershire, May 26, 1946. Educated at Marlborough and Keble colleges, Oxford, he was ordained in 1884, became canon of St. Paul's Cathedral and bishop of Stepney, London, in 1897, and was then bishop of London for 38 years (1901-1939), the longest tenure since the 17th century. A man of pervading democracy, kindness, and personal charm, Bishop Ingram became famous for his religious and social work in London's East End slum areas, an activity stemming chiefly from his appointment as head of Oxford House, Bethnal Green (an organization of religious and social workers from the university) in 1889, when he delighted in ringing doorbells to bring his message to the poor. His simplicity and his human characteristics, including athletic prowess, added to his popularity. In World War I he visited the Salonika and Western fronts; in 1926-1927, at 68, he undertook a world missionary tour during which he visited the United States, exemplifying his vitality in a whirlwind of engagements including talks at many universities, tennis with Helen Wills, and golf of fine quality. Among his many religious books, *What a Layman Should Believe* (1938)

reflected his adherence to the high church viewpoint in interpreting Church of England doctrine, while *Fifty Years' Work in London* (1940) described his life mission. He was knighted in 1915.

Consult Colson, Percy, *Life of the Bishop of London*, rev. ed. (London 1939); Carpenter, Spencer C., *Winnington-Ingram* (London 1949).

INGRAM, Frances, American contralto: b. Liverpool, England, Nov. 5, 1888. Brought to the United States at the age of nine, she was educated in Brooklyn, N.Y. In 1912 she made her debut as Lola in *Cavalleria Rusticana* with the Chicago Grand Opera Company. She sang with the Montreal Grand Opera Company (1913-1914); made concert tours in 1914 and 1915; sang with the Chicago company in 1915 and with the Metropolitan Opera Company in 1919. During her career she performed the title role in *Carmen*, that of Azucena in *Il Trovatore*, Ortrud in *Lohegrin*, Amneris in *Aida*, and many others.

INGRAM, John Kells, Irish scholar and writer: b. Temple Carne, County Donegal, Ireland, July 7, 1823; d. Dublin, May 1, 1907. In 1843 he was graduated from Trinity College, Dublin, and in the same year his poem, *The Memory of the Dead* (1798), was anonymously published, soon to become a rallying hymn for the Irish Nationalist cause. Ingram returned to serve Trinity College in several successive capacities, notably as professor of oratory and English literature (1852-1866), regius professor of Greek (1866-1877), librarian (1879-1887), and vice provost (1898-1899). A versatile scholar, he wrote books and periodical articles in the fields of philosophy, science, political economy, and mathematics—and poems, as well. His *History of Political Economy* first appeared in the 9th edition of *Encyclopaedia Britannica* in 1885 and it was revised and published in book form in 1888, going through 5 English editions and undergoing translations into 10 foreign languages. Among his other works are *Outlines of the History of Religion* (1900); *Sonnets and Other Poems* (1900); *Practical Morals* (1904); and *The Final Transition* (1905).

INGRASSIA, êng-gräs'syă, or INGRASSIAS, êng-gräs'syäs, Giovanni Filippo, Sicilian anatomist and physician: b. Regalbuto, Sicily, c. 1510; d. Palermo, Nov. 6, 1580. He studied at the University of Padua, graduating in 1537, and in 1544 became professor of anatomy and practical medicine at the University of Naples. In 1556 or 1563 he returned to his native Sicily and was appointed the island's chief physician, in charge of all medical services. He held this post until his death. During these years he worked to raise standards of public health, taking effective measures to suppress the plague at Palermo in 1575. Although highly esteemed for these efforts, he is principally known for his work in anatomy, especially in osteology and myology. Ingrassia did much valuable work in skull anatomy, including the discovery of the stapes, and he was the first to describe the seminal vesicles. Much of his pioneer work in osteology is contained in the treatise, *In Galeni librum de ossibus doctissima et expectatissima commentaria*, published posthumously in 1603.

INGRES, ăn'gr', Jean Auguste Dominique, French painter: b. Montauban, France, Aug. 29,

1780; d. Paris, Jan. 14, 1867. His father was a musician and sculptor, and the son early showed talent as a violinist. Inspired by the work of Raphael, however, he determined to be a painter, and therefore proceeded to Paris in 1796. There he studied with Jacques Louis David, supporting himself by playing in a theater orchestra. In 1801 he won the Prix de Rome for his painting, *Les ambassadeurs d'Agamemnon* (*The Embassadors of Agamemnon*), but because of the unsettled state of French finances was unable to go to Rome until 1806. After a stay of several years in Rome, he moved to Florence in 1819 and during the period in Italy supported his family by portraiture, producing also a number of other paintings. Among them were *Oedipe et le Sphinx* (*Oedipus and the Sphinx*, 1808) and *Odalisque couchée* (*Reclining Odalisque*, 1814), the latter eventually one of his most popular works. At the time, however, he received scant recognition for any of his paintings. Rejecting romanticism, his art was nevertheless affected by it, often revealing sensuous qualities associated with the romantic spirit. Thus, paradoxically, it was the romantics who first appreciated and accepted his work.

In 1824, Ingres returned to France with the painting, *Vœu de Louis XIII* (*Vow of Louis XIII*), done for the cathedral at Montauban. This work was an immediate success, and he was soon elected to the Institut de France (1825). Remaining in Paris until 1834, he enjoyed brilliant success as a painter, receiving many commissions for portraits and official paintings and attracting a large group of students. During this period he produced the *Apothéose d'Homère* (*Apotheosis of Homer*, 1827), and in the same year the *Odalisque* achieved fame in lithograph form. Ingres was now a leading exponent of conservatism, as opposed to the romanticism of Eugène Delacroix and his followers. He delighted in beauty of line for its own sake, his drawing often revealing a compromise between reality and his ideal of perfect symmetry. To his students he emphasized the importance of line, to the detriment of color. As subjects for inspiration he prescribed classic mythology and sculpture and Raphael's paintings.

Disappointed by the cool reception accorded his *Martyre de St. Symphorien* (*Martyrdom of St. Symphorien*, 1834), he decided to accept the post as director of the Académie de France à Rome. In Rome he continued with such paintings as *Odalisque à l'esclave* (*The Odalisque with the Slave*, 1840) and *Stratonice* (1840). When he returned to France in 1841, he was again hailed with enthusiasm. In 1845 came one of his best portraits, *Mme. d'Haussonville*, followed by the well-known *La source* (1856). Shortly after his death in 1867 the Musée Ingres was founded in Montauban with a large collection of his drawings and paintings. An excellent collection of Ingres' work may also be found in the Musée du Louvre in Paris.

INHALATION, in-hă-lă'shŭn, the breathing in of air or vapor. This is the physiological process by which oxygen is introduced into the human system. Steam inhalations are employed

in young infants particularly to dilute the sputum in the bronchi and prevent obstruction. Inhalation is the route employed to administer various drugs: notably anesthetic agents, resuscitants, antibiotics, and bronchial dilators. To guard against noxious substances being inhaled in the pulmonary system various inhaler filters have been devised to eliminate ingestion of industrial wastes, dust, silicon, and the products of incomplete combustion. This is an important public health problem.

REAUMUR S. DONNALLY, M.D.

INHAMBANE, ĩn-yămb-ă'ăně, town, Mozambique, overseas province of Portugal, situated on the East African coast on the Mozambique Channel of the Indian Ocean, 230 miles northeast of Lourenço Marques. It is the capital of the District of Inhambane (pop. 1950, 570,089). The town is a port for coastwise shipping, linked by railroad with Inharrime and by air with Lourenço Marques and other points. It exports the products of the region, including sugar, cotton, peanuts, rubber, corn, copra, mafura, and timber; and soap, bricks, tiles, and pottery are manufactured here. Inhambane was founded in the mid-16th century, and in 1834 was captured by tribesmen of Bantu stock (see also *MOZAMBIQUE—Government*). Thereafter the town declined, but it revived near the close of the 19th century. Pop. (1955) 68,117.

INHERITANCE, ĩn-hěr'ĭ-tăns, in law, a term used in a general sense to describe all property, real or personal, passing from a deceased person to others, either under the terms of a will or by operation of law. In this broad sense, any property distributed from a decedent's estate, whether pursuant to his will, or under the local laws of descent and distribution, or in accordance with a judicially approved agreement, constitutes an inheritance. Thus an agreement of brothers to pay their sister annually a sum of money from income of a trust created for them has been held to be an inheritance, where the agreement was made in compromise of the sister's threat to contest their father's will.

In a more limited and technical sense, and as used at common law, the term "inheritance" relates only to real property descending to an heir by operation of law, and not under a will. Thus used, the term excludes devises of real property and all distributions of personal property.

Even in its broad sense the term "inheritance" does not apply to the passage of the share of a joint owner to a surviving joint owner. (See also *JOINT TENANTS*.) Accordingly it has been held that where property is owned by a husband and wife, and the husband dies, the wife does not take the husband's interest by inheritance. It has similarly been held that, where a deceased person has held the record title to property in trust for another, the latter does not acquire the property by inheritance when the trusteeship is terminated by death. See also *DESCENT AND DISTRIBUTION*.

RICHARD L. HIRSHBERG.

INHERITANCE TAX, a term used in a broad sense to describe levies imposed upon the transfer of the property of a decedent at the time of his death. It also includes taxes imposed on property transferred "in contemplation of death," that is, where considerations of death were the predominant motive. It does not include taxes on

other gifts, though these are frequently imposed to prevent avoidance of death duties and are therefore treated as a satellite of the inheritance tax institution. Although insurance may technically involve transfer outside an estate settlement, the proceeds are also usually included in a death tax base.

In the narrower sense inheritance taxes are distinguished from estate taxes, the former based on the transfers by a decedent to specific heirs, the latter on the undivided or aggregate wealth transferred by a decedent to all his heirs. Estate taxes are generally regarded as simpler to administer and more productive of revenue, while inheritance taxes are considered a more refined application of the ability-to-pay principle. In the United States the federal government uses the estate tax exclusively, but the states employ predominantly the inheritance tax. Great Britain formerly used a combination of the two types of levies, but since 1949 it has confined itself to the estate tax.

Although the federal government of the United States had used death taxes as emergency measures during previous periods, it was not until 1916 that the estate tax was added as a permanent feature of its revenue system. State inheritance tax laws in some form date at least to the Pennsylvania law of 1826, but it was not until 1903, in Wisconsin, that graduation according to both size of transfer and relationship of heir to deceased was introduced. Federal encroachment upon what some regarded as the taxing province of the states caused some controversy; it was settled by compromise, under which state taxes within limits may be credited against the federal levy.

Inheritance taxes are supported mainly on the ground that they are in accord with the ability-to-pay principle and have a salutary effect on the distribution of wealth. They are said to make for "cradle equality," that is, to reduce the head start of youth who inherit what others have earned. These taxes are criticized on the score that they are especially inimical to the accumulation of capital—"grinding the nation's seed corn"—and that they dissolve socially desirable family-owned businesses.

Special features of death tax laws are perennial areas of litigation and legislative debate. This is true of gifts in contemplation of death, a status which turns on motivation and is not easily established. Legislative bodies have sought to mitigate the problem by specifying a period before death during which gifts are presumed to be "in contemplation." Gifts and bequests in trust, providing for successive life estates and a remainderman, are another such area; they can be used to cover several generations in one transfer and to extend the period between levies. Finally there are devices for splitting estates to avoid the full brunt of the graduated scale; this problem was compounded in the United States by the adoption of the rule of marital deduction, providing that spouses may succeed to half of an estate tax free.

At the state level, problems of jurisdiction and multiple taxation arise especially in the taxation of intangible property. Such property is now taxed predominantly at the domicile of the deceased, but two or more states may claim such domicile and no satisfactory means of resolving such disputes has been found. States also complain of migration to escape their death taxes; the federal credit has mitigated, but has not

eliminated this problem. Canada, with similar problems, has sought without complete success to nationalize the tax by agreements with the provinces. The same problems on a lesser scale arise between nations, but here they have been mitigated by many international agreements.

Death taxes generally are not major revenue producers and in the United States they provide less than 2 per cent of total tax revenue. This is despite a stiff federal rate schedule ranging from 3 to 77 per cent, the latter on portions of taxable estates above \$10,000,000. Critics blame the high exemption (\$60,000) and the avoidance of the tax, by the above-mentioned splitting and stretching, for this rather unimpressive showing. A death tax as a revenue producer has the inherent limitation that it reaches only part of the national wealth, and at most once in a generation. The persistent interest which the tax invokes is much greater than its yield.

HAROLD MARTIN GROVES,
Department of Economics, University of Wisconsin.

INHIBITION, ĭn-hĭ-bĭsh'ŭn, in psychology, the restraint of one activity by the presence of a conflicting mental process. This term has received considerable attention. In traditional speculative psychology, the ability of a person to inhibit responses was accounted for by reference to the faculty of the will. Attempts to extort confessions through torture might fail because the victim could, through the use of will power, inhibit both an overt expression of pain and an admission of certain information. Restraints of this sort came to be known as examples of purposeful inhibition. Inability to recall well-known facts, such as might occur when one is emotionally disorganized, were referred to as acts of unintended inhibition.

The first thoroughgoing analysis of the psychology of inhibition was made in 1816 by Johann Friedrich Herbart (q.v.). He taught that ideas have a permanent existence in the mind and that in many cases one idea conflicts with another. The stronger of the two ideas then inhibits the presence of the other in consciousness. The weaker idea, though it continues to remain in the mind, recedes out to the periphery of consciousness. The dynamic interrelations among ideas depend upon the time that they have been in the mind, their intensity, and their quality. According to Herbart, it should be possible to express in an equation the interplay between two ideas, one of which inhibits the other.

Sigmund Freud (q.v.) incorporated some of Herbart's views into his theory of repression. In his early writings Freud taught that, because of excessive repressions or inhibitions, a person may become overwhelmed by anxieties. Toward the end of his life, however, Freud taught that anxieties must be excluded from the conscious mind, lest the individual become disorganized. Only when the defensive, inhibitory barriers against unconscious urges have given way does the person develop a neurosis or a graver mental disorder.

Ivan Petrovich Pavlov (q.v.) investigated some of the mechanics of inhibitory processes in laboratory dogs. He found that if the animal is trained to respond to a regular signal when food is presented, eventually the signal alone will induce salivation. This he termed a simple conditioned response. The dog would be inhibited in responding to any signal other than that regularly

used in the training. When he attempted to train dogs to make conditioned responses to extremely complex situations, some of them lost all their inhibitions. They would growl, tremble, cower, and exhibit many other symptoms of complete disorganization. He had created what he called an experimental neurosis. The condition is somewhat like that in the human being who is in the state popularly called a nervous breakdown. The discriminations and the inhibitions of normal everyday life are replaced by purposeless, disorganized behavior.

The self-protective inhibitions may be weakened by mental disorders, illnesses, or drugs. A mild, quick-acting barbiturate may lower a person's level of inhibitions and may facilitate the disclosure of data which normally would not be revealed. Such information may be helpful to a psychiatrist who wishes to help his patient to understand the unconscious dynamics behind a mental disorder. Other techniques, wholly unethical, are used in disorganizing personality through the destruction of normal inhibitions. Prolonged malnutrition, induction of excessive fatigue, an admixture of kindly and brutal treatment—these are some of the methods used in so-called brainwashing, which, in essence, is the removal of all self-protective inhibitory controls from its victim.

PHILIP L. HARRIMAN,
Professor of Psychology, Bucknell University.

INIA, ĭn'ĭ-ă, a genus of toothed freshwater cetaceans similar to dolphins (family Delphinidae), but belonging to the allied family, Platanistidae, subfamily Iniinae. The single species (*I. geoffrensis*), the Amazon River dolphin, also called boto, is found in some of the upper tributaries of the Amazon. It measures about 6 to 9 feet in length and has a long narrow snout with 26 to 33 peglike teeth in each side of the jaw (total 104 to 132). The color varies widely from light pink to gray or black, and is frequently darker above and lighter below. The dorsal fin, located on the rear half of the back, is long and low. Fish is its principal food.

R. L. PETERSON.

ININI, ĭ-nĕ-nĕ', district, French Guiana, bounded on the north by the coastal strip of French Guiana, on the east and south by Brazil, and on the west by Surinam. The boundary with Brazil is formed by the Oyapock River on the east and the Tumuc-Humac Mountains on the south, while the Surinam boundary is formed by the Maroni River. It is a densely forested, sparsely populated area of 30,300 square miles with many swift, but navigable, rivers. Its products include rosewood and other cabinet woods, balata gum, and alluvial gold. There are no towns, only a few small outposts. Formerly separately administered by a decree of 1930, it was reunited with the French overseas Department of Guiana by a law of 1946 and was made a separate *arrondissement* (district) in 1951. The inhabitants are largely Negroes, mixed breeds, and Indians. Pop. (1954) 3,234.

INITIAL DIP. See DIP.

INITIATION, ĭ-nĭsh-ĭ-ă'shŭn, the rites with which an individual is admitted to a society or social group, or which mark the transition from one state to another, as passing into maturity or

into a special state of sanctity. Among primitive peoples the ceremonies initiating male children to adult status are most widespread and assume paramount importance. Such ceremonies take place at about the time of puberty, but primitive thought emphasizes the social importance of this transition and the new privileges and responsibilities which are involved. Thus the youth must demonstrate his ability to undertake these responsibilities by proving his endurance and courage. He is tested by physical pain or discomfort, as in fasting, whipping, knocking out a front tooth, circumcision, or other permanent mutilation of the body. The novices are usually initiated in a group secluded from women and uninitiated children, for now the elders give instruction in the duties of a man and reveal the religious mysteries of the tribe. Thus, among some tribes of American Indians, the initiates learn that the dancing "spirits," whose appearances they had feared as children, were in reality masked men. Women and the uninitiated may not witness any of these ceremonies on pain of death and they may not know the magical mysteries which form so important a part of the tribe's religious life.

Among many savage tribes the concept of death and rebirth is associated with this period of seclusion and initiation. In some tribes of Australia and New Guinea the youths are swallowed and disgorged by a mythical monster, whose roar is produced by men swinging bull-roarers. Women and children who hear the humming sound believe that this is the voice of the monster. Among tribes which practice totemism the ceremony of death and rebirth is associated with the totem. The novice dies as a human being, but comes to life as an animal, the soul of the totem animal being now in his body, and thus he is related and linked in a special way with animals of that species.

In primitive societies initiation to special groups generally involves ceremonies similar to those at puberty. For instance, some religious associations of North American Indians are open only to candidates who have gone through the ceremony of death and resurrection.

INITIATIVE, i-nish'î-tiv, in government, the method by which voters themselves may propose and enact a new law. The process was first developed in Switzerland. Early in United States history the initiative was inaugurated by some states for the purpose of making constitutional changes, but North Dakota was the first to allow it for general lawmaking (1898). Nineteen states have followed suit, Mississippi being the last state to adopt it (1916).

The procedure calls for a petition containing a draft of the proposed law and signed by a specified number of voters, the number varying according to the laws of the several states. Often the number is expressed as a certain percentage of the registered voters. If the petition qualifies, the proposed act is placed on the ballot, in some states, while in others it is submitted to the legislature first, being set before the voters only if defeated by the legislature. If a sufficient number of voters approve the measure, it then becomes law. See also **REFERENDUM**.

INJECTION, in-jêk'shûn, the process by which fluids are administered to the animal organism, primarily human. Ordinarily such fluids are given by a glass syringe, consisting of a barrel

and a plunger, the barrel marked off in cubic centimeters and possessing a tip for insertion in the hub of a stainless steel needle. Special types of syringes include the tuberculin, calibrated in hundredths of a cubic centimeter for allergy testing; and the insulin syringe, where the administered dose is written on the barrel. Through the use of a special metal tip, the Luer lock, the needle may be locked to the syringe by giving it a quarter turn.

There are three general types of injections: The first, called hypodermic, is an injection given under the skin (subcutaneously) in the soft tissues. This type is used for common sedatives, such as the barbiturates and morphine; routine inoculations against infectious diseases, such as typhoid, yellow fever, and tetanus; and anti-allergenic inoculations, for example, those against ragweed, tree, or grass pollens. The second type of injection, the intramuscular, is the route used for more painful and longer-acting medications, such as the B-complex vitamins, the antibiotics (penicillin and streptomycin), the heavy metals (the mercurial diuretics), and oil suspensions (notably the male and female hormones). The last usual type of injection is by vein (intravenous). The solutions are physiological, so as to be compatible with blood. They are packed in sterile glass bottles, fitted with an air intake tube and a drip chamber to measure flow, and are fed to the vein by gravity through disposable plastic tubing. Intravenous injections are invaluable in restoring blood volume with plasma and in maintaining body electrolytes.

REAUMUR S. DONNALLY, M.D.

INJUNCTION, in-jûngk'shûn, in law, an order or command of a court prohibiting or requiring the doing of certain acts. It is primarily a preventive remedy directed against future acts, but it may also be aimed toward the reversal of past actions and the restoration of the status quo. Although the issuance of injunctions is within the inherent power of equity courts, statutes sometimes define or restrict the remedy and specify the procedural steps necessary to obtain, modify, or dissolve an injunction.

Classification.—Injunctions may be classified, according to their effect, as prohibitory or mandatory. A prohibitory injunction restrains the commission or the continuance of an act. A mandatory injunction, on the other hand, requires the taking of affirmative action. Such injunctions are used to compel the abatement of nuisances, the removal of buildings and obstructions, the transfer of title or possession, and for other similar purposes.

Injunctions may also be classified as preliminary or final. The primary purpose of the former type, which is also sometimes called temporary or interlocutory, is to prevent threatened wrongs and to preserve the status quo until the holding of a final hearing. Notice to the respondent and a preliminary hearing are usually required before a preliminary injunction will be granted. The question of granting or refusing such an injunction is left to the sound discretion of the court and depends upon whether the complainant can show an urgent necessity for relief prior to the thorough investigation of the case. A bond or other security is frequently required in connection with obtaining such an injunction. The issuance or the withholding of a preliminary injunction, not being a final order, is ordinarily not

reviewable by a higher court. Closely related to a preliminary injunction is a temporary restraining order, the purpose of which is also to preserve the status quo. This type of order requires the respondent to appear on a certain day and to show cause why a temporary injunction should not be issued. A final or permanent injunction is issued after the hearing of a case on the merits, and the granting or refusal of such an injunction is a reviewable order.

Another type is the ancillary injunction, an order issued by a court either to protect its own jurisdiction and to make its judgment effective or to aid proceedings in another court.

Issuance.—Injunctions are ordinarily issued by courts of equity rather than by tribunals possessing strictly common-law jurisdiction. In most cases the court must be satisfied that a suit for damages or any other ordinary legal action would be inadequate. This does not mean that there must be a total lack of legal remedy in order for a complainant to invoke equity jurisdiction. In an appropriate case, an injunction may be granted where a remedy at law exists, but is not sufficiently complete or prompt to effect substantial justice.

The remedy at law is considered to be inadequate, so as to justify the grant of an injunction, where the injury is irreparable or where a multiplicity of suits would be necessary in order to redress the wrong. On the other hand, if the injured party can obtain full relief through a single action at law for damages or through some other single lawsuit, an injunction will be refused on the ground that the remedy at law is adequate. Irreparable injury is a technical term which is not construed in its literal sense. It may mean that complete compensation for the wrong in question cannot be made by the payment of damages or, alternatively, that the amount of damages is difficult or impossible to measure. The term may also refer to the fact that the injury is continuous or repeated or that the wrongdoer is unable to pay damages because of insolvency.

The term "multiplicity of suits" may refer either to the number of actions which the injured party would have to bring in order to obtain complete redress by way of damages or to the possibility that the person seeking the injunction might himself be repeatedly harassed by lawsuits. Examples of circumstances under which courts of equity will grant injunctions because the complainant would have to bring a succession of lawsuits to obtain sufficient relief are cases of nuisance, waste, trespass to land, and disputed boundaries, in which the wrong complained of is by nature continuous or repeated. An example of vexatious actions against a complainant in an injunction suit is the situation where he has been subjected to a series of actions of ejectment to recover the same tract of land. In such a case, equity will interfere and grant an injunction prohibiting further lawsuits, provided that the complainant's legal title to the land has been clearly established. Similarly a court may issue an injunction to prevent repeated attempts to enforce the collection of invalid taxes.

Property Rights.—Traditionally the rights which equity will protect by injunction are property rights. The protection afforded extends to property both real and personal, both tangible and intangible. The remedy is frequently resorted to for the prevention of such torts as recurring trespasses, nuisances, and injuries resulting from

the pollution, obstruction, or diversion of waters. Injunctions will not usually be granted for recovery of possession of real or personal property, inasmuch as conventional legal remedies, such as ejectment or replevin, are adequate. For the same reason the invasion of personal rights, as distinguished from property rights, will not generally be enjoined. The tendency of modern courts, however, is to extend the definition of property rights to include all rights of a pecuniary nature. Similarly some statutes expressly authorizing the injunctive protection of personal rights have been enacted. Political rights will not, as a rule, be protected by injunction, and the courts will not enjoin acts which are solely criminal and do not affect property rights.

Contracts.—Injunctions are often granted to prevent breaches of contract. For example, a person may be restrained from accepting a new employment where the services which he has contracted to perform for his present employer are unique or extraordinary, as in the case of writers, entertainers, and professional athletes. Contractual restrictions on entrance into a competing business or professional practice are also enforceable by injunction.

Equity.—The grant or denial of an injunction is governed by general equitable principles and is largely dependent upon the sound discretion of the court. As in the case of other remedies, a court will not issue an injunction which it lacks the power to enforce. No jury trial is provided, and in most cases there is no absolute right to an injunction. It will not be issued if the complainant has been guilty of misconduct, fraud, or unfairness in connection with the subject matter of the injunction suit, nor will it be granted at the request of a person guilty of unreasonable delay operating to the disadvantage of the other party. For example, if a complainant seeking an injunction to compel the removal of buildings encroaching upon his land had allowed a long period of time to pass and had allowed the respondent to make large expenditures for the erection of the buildings without attempting to stop him, a court would probably refuse his request for an injunction. This sort of defense to an injunction suit is known as laches, or acquiescence. Lapse of time alone does not constitute the defense, since it must be shown that the complainant had actual knowledge or adequate means of knowledge in order for the delay to be held unreasonable. Similarly, if the delay is excusable, such as might be caused by the respondent's promises to remedy the wrong, the doctrine of laches does not apply.

In order to obtain an injunction a complainant must show a clear right or title which he seeks to protect, since the question of title and other rights in property will not ordinarily be tried in an injunction proceeding. The complainant must demonstrate the existence or the real threat of substantial injury to his rights, as a court of equity will not interfere, if the suit is based upon a mere possibility or apprehension of harm or if the injury threatened is trivial. Injunctions will not be granted to prevent the doing of lawful acts, such as conducting a legitimate business, disposing of one's property as one chooses, or enforcing a debt, though others may be incidentally harmed.

INJURIES, Industrial. See ACCIDENTS, CAUSES AND PREVENTION OF.

INJURY, in law, an act by which the rights of another person or of the state are violated and for which the party whose rights are so invaded may institute action for damages against the perpetrator. Wrongs called *damna absque injuria* are those acts which while injuring another do not permit the latter the right to enter an action, there being no remedy for such acts. See also CRIME; CRIMINAL LAW; LIABILITY INSURANCE; TORT.

INK, a colored liquid used for writing; also a liquid or paste used for printing. Of the many varieties of ink the oldest known is India or China ink which is thought to have been used in China as early as 1200 B.C. Usually marketed in dry cakes or sticks, India ink is made of lamp-black or ivory black mixed with glue or a gum. Its rich blackness and permanence are distinctive qualities. Sepia, extracted from the squid, octopus or cuttlefish, was used as an ink in ancient times. Nutgall ink, made of nutgalls and copperas (green vitriol), seems to have been known as early as the 2d century A.D. It is essentially the standard black ink of commerce today; however, the tannic acid constituent is now generally supplied by some other substance than nutgalls.

The following are some of the more important kinds of inks:

Aniline.—An aniline dye solution in a volatile solvent or dilute gum, used for printing in bright colors, or at high speeds.

Cancelling.—Suspension of lampblack in oil, used for stamp pads.

Copying.—An iron-tannic acid ink.

Diamond.—Mixture of barium sulfate and hydrofluoric acid used for writing on glass.

Fugitive.—When treated with water, or bleaching chemicals, it disappears; used for printing bank checks.

Invisible, Secret, or Sympathetic.—Normally invisible, such inks (there are many varieties) become visible when the writing is exposed to heat, light, water, or particular chemicals.

Printing.—There are three types: (1) pigment suspension in a mineral oil, or in a drying oil; (2) aniline; and (3) a warm molten resinous pigment for high-speed printing.

INK DRAWING. See ART DRAWING.

INKBERRY or WINTERBERRY, an evergreen shrub (*Ilex glabra*) of the holly family native to the Atlantic coast from Massachusetts to Florida, also to Alabama and Mississippi. Its slender and flexible stems are two to four feet high and its leaves, about an inch in length, are lanceolate, of leathery texture, and present a shining upper surface. It bears small, very black berries which are valued for decoration. Formerly its bark and leaves were used medicinally, especially for fevers.

INKERMAN, ینگ'کەر-مان, village, USSR, on the site of a ruined town in the Crimea, at the head of the harbor of Sebastopol, at the

mouth of the Chernaya River. It gives its name to the sanguinary battle fought on the heights overlooking the town, on Nov. 5, 1854, when the Russians unexpectedly attacking the British camp were repulsed with great slaughter on both sides. In World War II it was captured by the Germans on June 28, 1942.

INLAYING is the art of producing an ornamental surface by inserting varicolored forms and substances and reducing the whole to a smooth uniform condition, but with a pattern formed by the contrasting material introduced. Its essential difference from mosaic work is that mosaic (q.v.) is mainly made up of very small surfaces, while inlaid work is additional to a surface, as of ivory on wood, already existing, to add to its beauty. Various kinds of metal or wood, or pearl and ivory, are employed in this process, which is now applied chiefly to the production of ornamental articles of furniture. When wood of one color is inlaid with others of different colors, as in ornamental devices in flooring, it is generally called parquetry, the various pieces of wood being usually disposed in regular geometrical figures. Marquetry is simply the French term for inlaying. The art of inlaying iron or steel with other metals, as gold or silver, is called damascening. Boulle (or buhl) and riesener work, once highly prized, have lost much of their celebrity. The former is named from Charles André Boulle, an Italian cabinetmaker to Louis XIV, and the latter from Jean Henri Riesener, a Franco-German cabinetmaker to Louis XVI. Boulle for the most part inlaid brass on tortoiseshell, Riesener a dark wood on a tulip-wood ground. The usual instrument for cutting out veneers for inlaying is a fine saw, mounted in a bow or arched handle, and worked in short quick movements. Three or four veneers are sometimes cut simultaneously in this way. Inlaying with stone, a Florentine specialty, is called *pietra dura*, and differs from mosaic in having the holes not cut through the ground, which is commonly of black marble, but only to a regulated depth.

INMAN, Henry, American artist: b. Utica, N. Y., Oct. 28, 1801; d. New York, N. Y., Jan. 17, 1846. From early boyhood he manifested a taste for art, and in 1814 John W. Jarvis, the portrait painter, offered to receive him as a pupil, and he was bound an apprentice for seven years. After completing his apprenticeship he devoted himself to portrait painting. In 1832 he married and settled at Mount Holly, near Philadelphia. He was a founder of the National Academy of Design and one of its vice-presidents. Among his most characteristic portraits are those of Chief Justice John Marshall, Marquis de Lafayette, William Penn, Martin Van Buren, Fitz-Greene Halleck, John J. Audubon, DeWitt Clinton, Clara Barton, and Bishop William White. Many of his portraits are in public buildings in New York, Albany, and Philadelphia. He also painted landscape and genre scenes. His portrait of the poet William Wordsworth, made while he was in England in 1844-1845 and now at the University of Pennsylvania, is one of his best known.

INN, a river of Europe which issues from a lake at the foot of the Piz Longhino in the Rhaetian Alps, at an altitude of about 8,000 feet, forms a series of small lakes, the best known of which is that of Saint Moritz, then flows

northeast through the deep, narrow Engadine valley in the Swiss canton of Graubünden (Grisons). It enters Austria at Finstermünz Pass in the Tirol, passes Innsbruck, Solbad Hall, and Kufstein, and flows into Germany through the Bavarian Alps. At Mühldorf it turns east and finally empties into the Danube at Passau. Running a course of over 300 miles, it drains an area of approximately 10,000 square miles. Because of its rapid current, it is of little importance as a navigable river, but it is used to bring timber down to the Danube from the forests of its upper regions. There are many hydroelectric plants on its upper course, and agriculture is extensive in the more fertile lower valley. It forms the border between Germany and Austria from its confluence with the Salzach, its most important tributary, to Passau.

INN, a public house for the commercial lodging of travelers. Inns have existed since Biblical and Roman times, when a bush attached to a roadside stake was the sign of an inn. Following a decline during the barbarian invasions, the demand for inns grew with the increase in travel consequent on pilgrimages, crusades, and expanding trade, and by the 14th century more distinctive inn signs had appeared. A prominent feature of most inns in coaching days was the courtyard, where passengers were discharged. The large room of the market town inn served as an assembly hall. With the advent of the railroad, roadside inns declined, but they have revived with automobile travel in the 20th century.

Early innkeeping standards were crude, but as travel and competition developed, facilities improved, and minimum standards were established by government regulation. The luxurious modern hotels and motels are developments of the original inn, which now exists for the most part only in country districts. See also **HOTELS**.

RICHARD E. WEBB.

INNATE IDEAS, *in'nāt*, ideas with which a person is born or, less strictly, which are at least not learned, abstracted, or compiled from sense perception. Many theologians, philosophers, and psychologists have thought that such ideas exist and are the bases of religion, morality, mathematics, logic, or common sense. The term "innate ideas" is thus used both for bare concepts (such as God, justice, number, or physical objects) and for a grasp of truth about the corresponding objects (such as the existence of God, the laws of justice or number, and so forth). Innate ideas are supposed to be peculiarly (1) universal, in that they both apply very generally and are accepted very widely; (2) certain, in that the mind cannot doubt them and that they are in fact infallible; and (3) necessary, in that they could not be otherwise and that rational life would be impossible without them. Though they are especially intimate traits or acts of the individual spirit, they are supposed nevertheless to plumb most deeply and truly the nature of things in themselves.

Plato (427?-347 B.C.), probably influenced by the Pythagorean belief in reincarnation, gave an early and charming account of innate ideas. To explain how even the untutored can appreciate proofs about ideal geometrical objects never met in experience, he conjectured that every soul brings into this life a memory of a previous contemplation of the pure forms on which

mundane things are modeled (these forms are "ideas" in the special Platonic sense), and that diagrams or argument only recall this knowledge to us. His similar suggestions about the evocative power of beauty are echoed by some modern poets such as Percy Bysshe Shelley and William Wordsworth.

Many ancient thinkers, independently of Plato, distinguished some fundamental ideas and beliefs as especially natural and common, and Cicero (106-43 B.C.) called these "innate." Christianity taught that there is a kind of natural revelation of principles essential to human existence—religious, moral, metaphysical, and logical—which God imparts to all peoples. At the Renaissance, this seemed at first rather confirmed by new anthropological discoveries, while great scientific successes both in pure mathematics and in celestial and terrestrial mechanics encouraged the notion of a "natural light" which needs only maturity and opportunity to divine the truth. René Descartes (1596-1650) may have meant by "innate ideas" no more than this faculty of reason. However, the monadism of Gottfried Wilhelm von Leibniz (1646-1716) described all knowledge as a becoming explicit of what was always implicit in the learner's essence. More religious writers, particularly the Cambridge Platonists in England such as Henry More (1614-1687), revived a trust in literal innateness.

There resulted an extreme empiricist reaction. John Locke (1632-1704) and later Voltaire (1694-1778), drawing on a better informed anthropology and on common sense, easily made fun of any pretense that babies and savages are acquainted with such esoteric principles as Platonism boasted. They returned to the maxim, no less ancient, that the mind starts as a blank tablet (*tabula rasa*) on which experience does the writing. Scholasticism had long had the maxim, not always strictly observed, "There is nothing in the intellect which has not been in the senses," and David Hume (1711-1776) repeated that all ideas are derived from impressions. When such empiricism admitted a priori truth at all, it meant not that its content is conceived independently of experience but only that, once conceived, its necessity is evident without perceptual induction or sampling. Empiricism, or sensationalism as it is called in the extreme version of Étienne de Condillac (1715-1780), largely prevailed among philosophers and scientists in England and France.

It was evident, however, despite Condillac's description of how a statue might be educated by experience, that experience in fact teaches nothing to statues, but only to beings with a certain innate organization. Thomas Reid (1710-1796) and other Scottish realists restored an emphasis on universal deliverances of common sense which verged on innatism. Even George Berkeley (1685-1753), generally an empiricist in denying that any ideas are strictly innate, had believed in "notions" which are autonomous acts of mind and yet penetrate to reality as mere "ideas" do not. Later, idealism was widely successful with the Kantian (Immanuel Kant, 1724-1804) and post-Kantian doctrine that the structure if not the content of experience is due to a transcendental power of the mind. "Nativism" in late 19th century psychology stressed that not even sense perception would be possible without some inborn principles by which it is ordered, and the evolutionism of Herbert Spencer (1820-1903) and Charles Peirce (1839-1914) argued that living

things must inherit more or less salutary habits of conception and belief from fortunate ancestors, so that ideas, like instincts, have a certain innateness in the individual though acquired in the race. The dispute, therefore, without being settled, lost vigor, and was absorbed in such general questions as the philosophical problem of a priori knowledge and the biological one of the relative roles of environment and heredity. See also *IDEA*.

DONALD C. WILLIAMS,
Professor of Philosophy, Harvard University.

INNER MONGOLIA, in'ēr mōn[g]-gōl'yá, officially now called the INNER MONGOLIAN AUTONOMOUS REGION (IMAR), an administrative unit of the People's Republic of China, founded on May 1, 1947. It includes large portions of the traditional Inner Mongolian provinces of Chahar, Suiyuan, Ninghsia, Jehol, and part of Kansu, north of the Great Wall, and also (since January 1948), the Barga area of western Manchuria. Kùke Khoto (Kuei-hua) serves as capital of the region, and the dominant political figure has for many years been the Communist, Ulanfu (Yun-tse, b. 1905). In the Ordos region, formed by the great bend of the Yellow River, extensive industrial expansion attends the contemporary development of the city of Paotow as a major steel-producing center of China. Also in the Ordos, Ejen Khoro is famed as the site of the purported remains of Genghis Khan (q.v.). The 1953 census of China reports 1,462,956 Mongols (most, but not all, of whom live in the IMAR), and a total IMAR population of 6,100,104. Chinese farmers constitute the main non-Mongol element of the population. See also *MONGOLIA*.

INNER RHODES or **INNERRHODEN**.
See *APPENZELL*.

INNESS, in'ēs, **George**, American painter: b. near Newburgh, N.Y., May 1, 1825; d. Bridge of Allan, Scotland, Aug. 3, 1894. The son of a prosperous merchant, he spent his boyhood in Newark, N.J. At the age of 16 he was employed by an engraving firm in New York City, but left the company after a year to devote all his time to painting. He exhibited at the National Academy of Design in 1844 and soon opened his own studio; he had had a few drawing lessons but was practically self-taught. Though his work of this period was rather stiff, it showed his talent for depicting landscapes, in which he specialized. In 1847 he went to paint in Italy for a year, returning there with his wife in 1851 for a longer period; in 1854 they went to Paris, where he was profoundly influenced by the work of painters of the Barbizon school. (See *BARBIZON, THE PAINTERS OF*.) After they returned to the United States, they lived in Medfield, Mass., where Inness painted some of his best-known pictures, and eventually settled in Montclair, N.J. He was elected to the National Academy in 1868, but for many years his paintings sold poorly. About 1875, however, the interest of Thomas B. Clarke and other rich collectors established a vogue for his work, and he enjoyed fame and financial success thereafter. He died while traveling in Scotland.

His early works, which are somewhat literal and quite detailed, show the characteristics of the Hudson River school. A typical example from this period is *Peace and Plenty* (The Metropolitan Museum of Art, New York City). In time he developed a freer, more individual style, and a calm lyrical quality replaced his earlier dramatic romanticism. Among his better-known canvases are *Georgia Pines*; *September Afternoon* (National Gallery of Art, Washington, D.C.); *Autumn Oaks*; *Spring Blossoms* (The Metropolitan Museum of Art); *Home of the Heron*; and *Millpond* (Art Institute of Chicago).

Consult Inness, George, Jr., *The Life, Art, and Letters of George Inness* (New York 1917); McCausland, Elizabeth, *George Inness, an American Landscape Painter* (New York 1946).

INNESS, George, Jr., American painter: b. Paris, France, Jan. 5, 1854; d. Cragmoor, N.Y., July 27, 1926. The son of the famous American landscape artist George Inness (q.v.), he began to study with his father about 1870 and worked with him in Rome until 1874. He then went to Paris where he studied with Léon Bonnat. After his return to the United States, he shared a studio with his father, but maintained one of his own in Paris from 1895 to 1899. He exhibited every year at the Paris Salon, receiving honorable mention in 1896 and a gold medal in 1900. Elected to the American National Academy in 1899, he was made an officer of the French Académie des Beaux Arts in 1902. He was well known for his animal pictures and also for landscapes in a style similar to his father's later works. Two of his best-known paintings, *The First Snow at Cragmoor* and *Shepherd and Sheep*, are in The Metropolitan Museum of Art in New York City.

INNOCENT, in'ō-sēnt, the name of 13 popes, as follows:

INNOCENT I, SAINT: b. Albano, Italy; d. March 12, 417; r. 401-417. As successor of Anastasius I, he became pope in 401, and although little is known of him personally, the record of his actions in ecclesiastical affairs for 16 years shows him to have been capable, vigorous, and energetic. He advised the bishop of Rouen, St. Victricius, that questions of importance should always be referred to the Holy See, and he sent the same instructions to the bishops of Spain and Africa. An advocate and exponent of clerical celibacy, he is most famous for the support he gave to St. John Chrysostom in his difficulties at Constantinople. Innocent's approval of the acts of the councils of Carthage and Milevis (416) was announced to the people of Hippo by St. Augustine in terms which gave rise to the adage *Roma locuta, causa finita est* (Rome has spoken, the case is closed). During his reign the barbarians crossed the Rhine (Dec. 31, 406), and the Goths sacked Rome (410). His feast is observed on July 28.

INNOCENT II (GREGORIO PAPARESCI): b. Rome; d. there, Sept. 24, 1143; r. 1130-1143. His ecclesiastical career began about 1080, and he was made a cardinal in 1116 by Paschal II. He served in the Curia under Gelasius II, Calixtus II, and Honorius II. After the death of Honorius in 1130, Innocent was elected pope by a group of the cardinals; but the ceremonies were not yet completed when another and larger group of them elected Pietro Pierleone, who took the name of Anacletus II. The question of the legality of

these elections is one of the most interesting and thorny problems in papal history. The possession of the Roman See was in dispute between the two rival popes until 1138, when Pierleone's death ended the schism; in the following year Innocent called the Second Lateran Council to repair the damage it had caused. (See *LATERAN COUNCILS*.) Apart from these difficulties, he devoted himself to effecting a moral reformation, condemning dogmatic errors, and settling conflicts on relations between church and state. He is remembered for his condemnation of Abelard and of Arnold of Brescia as heretics.

INNOCENT III (LOTARIO DE' CONTI): b. Anagni, Italy, 1160 or 1161; d. Perugia, July 16, 1216; r. 1198–1216. Educated at Paris and Bologna, he went to Rome about 1185, took minor orders, and was made a canon of St. Peter's. He was ordained subdeacon in 1187, and made cardinal deacon of Saints Sergius and Bacchus under Clement III. On the very day of Celestine III's death (Jan. 8, 1198), Innocent was elected to succeed him. He considered the medieval Christian world to be essentially one community in which the spiritual authority should, by right, dominate the temporal. This policy led to a multiplicity of conflicts with the sovereigns of the day and to an overgenerous application of ecclesiastical censures. As a result, spiritual penalties, by undue familiarity, lost much of their terror. At various times he deposed, excommunicated, or interdicted almost every king in Christendom.

His greatest political victory occurred in consequence of a dispute over the election of the archbishop of Canterbury. When King John of England opposed the nominee of the Holy See, Innocent placed England under interdict (1208), excommunicated John, and finally in 1212 deposed him. Threatened with invasion by King Philip II of France, John capitulated to the pope and in 1213 made the crown of England vassal to the Holy See. When, in 1215, the barons forced John to sign Magna Carta, Innocent declared the document null and void, on the ground that it had been extorted from his vassal by violence.

Strong as a protector of the faith, he launched (1202) the Fourth Crusade, which resulted in the temporary union of the Greek and Roman churches, and sent an army (1208) against the Albigensian heretics when they failed to yield to persuasion. (See *CRUSADES—Fourth Crusade; ALBIGENSES*.) In 1215 he convened the fourth and most important of the Lateran Councils (q.v.), at which numerous doctrinal issues were settled and another crusade proclaimed. In the inner government of the church he made significant reforms and fostered the initial rise of the Franciscan and Dominican orders. Innocent's tireless activity, full consciousness of his rights and duties, and enormous but disinterested ambition raised the high medieval concept of the papal monarchy to its zenith during his reign.

INNOCENT IV (SINIBALDO DE' FIESCHI): b. Genoa, Italy, c. 1190; d. Naples, Dec. 7, 1254; r. 1243–1254. Educated at Bologna, he became one of the most celebrated canonists of his day. Gregory IX made him a cardinal in 1227, and vice chancellor of the church at Rome in 1228. After the papal chair had been vacant for a year and a half, he was elected pope in succession to Celestine IV on June 24, 1243. He was a follower of the political policies of Innocent III, and his reign was a continual contest between himself and Frederick II, the Holy Roman emperor.

Obligated to flee from Rome to Lyon, Innocent directed a war against Frederick. The latter was defeated by papal troops at Parma in 1247, but his hold on northern Italy was so strong that the pope could not return to Rome until after Frederick's death in 1250. He blessed the crusade undertaken by Louis IX of France in 1248, encouraged missions in various parts of the world, and aided such universities as the Sorbonne in Paris. His *Apparatus in quinque libros decretalium*, first printed at Strasbourg in 1477, provides an excellent commentary on the decrees of Pope Gregory IX and was long considered a classic in canonical literature.

INNOCENT V, BLESSED (PIERRE DE TARENTAISE): b. Tarentaise, Savoy, France, c. 1225; d. Rome, June 22, 1276; r. Jan. 21–June 22, 1276. Having entered the Dominican Order at an early age, he studied theology at the University of Paris, where he took a doctor's degree and became a professor in 1259. That same year he was associated with Thomas Aquinas, Albertus Magnus, and 10 other members of the order in drawing up a curriculum of study which still remains the basis of Dominican teaching. He produced various works on theology and philosophy, including his highly esteemed commentaries on the *Sentences* of Peter Lombard. In 1272 he was appointed archbishop of Lyon and the following year became cardinal bishop of Ostia. An adviser to Pope Gregory X, he took a prominent part in the general council held at Lyon in 1274. He was unanimously chosen to succeed Gregory X on Jan. 21, 1276, but died after only five months as pope. During his short pontificate he promoted peace among the warring Italian states and worked to cement the union of the Byzantine Church with the Latin Patriarchate which had been arranged at the Council of Lyon. His cult as a beatus was confirmed by Pope Leo XIII in 1898, and he is described in the Roman Martyrology as one who "strove for concord among Christians."

INNOCENT VI (ÉTIENNE AUBERT): b. Monts (in present Corrèze Department), France; d. Avignon, Sept. 12, 1362; r. 1352–1362. First a professor of civil law at Toulouse, he became bishop of Noyon (1338), bishop of Clermont (1340), and a cardinal (1342). In 1352 he was made cardinal bishop of Ostia and Velletri and was named Grand Penitentiary. Later that year when The College of Cardinals met at Avignon to elect a pope to succeed Clement VI, they agreed that the one who was elected would share his powers with the college. Proclaimed pope on December 18, Innocent soon annulled the agreement.

He required the higher clergy to observe the laws of residence in their sees and urged members of religious orders to adhere to their rules of monastic discipline. He became involved in a lengthy dispute with Pedro of Castile, who wished to put aside his wife, Blanche de Bourbon, whom the pope sustained in the litigation. Innocent approved the coronation in 1355 of Charles IV as Holy Roman emperor, but the following year Charles issued the famous *Bulla Aurea* (see *GOLDEN BULL*), in which he attempted to annul the right of popes to confirm the election of rulers of the Holy Roman Empire. Innocent ignored this feature of the bull. He founded the Collège de St. Martial at Toulouse (1359) and a theological faculty at Bologna (1360). Though his reign was not free from nepotism, he was one

of the few reformists of his time and is considered one of the best of the Avignon popes.

INNOCENT VII (COSIMO DE' MIGLIORATI): b. Sulmona, Italy, c. 1336; d. Rome, Nov. 6, 1406; r. 1404-1406. Named archbishop of Ravenna (1387) and bishop of Bologna (1389), he became a cardinal on Dec. 18, 1389, and the following year Boniface IX sent him as papal legate to Lombardy and Tuscany. He was elected to succeed Boniface in 1404, but as this took place during the Western Schism, his claims to the papacy were opposed by Benedict XIII of Avignon. In an uprising in Rome his nephew Ludovico de' Migliorati, whom he had made a cardinal, murdered a group of the Roman leaders, and the anger of the people forced the pope to flee to Viterbo in 1405. When the Romans realized that he was not responsible for his nephew's crime, they again submitted to his authority, and he returned to Rome in 1406. He is remembered chiefly for his restoration of the University of Rome.

INNOCENT VIII (GIOVANNI BATTISTA CIBO): b. Genoa, Italy, 1432; d. Rome, July 26, 1492; r. 1484-1492. After studying at Bologna and Rome, he was made bishop of Savona (1467), bishop of Molfetta (1472), and a cardinal (1473). On the death of Sixtus IV, he was elected pope in 1484. In 1486 he acknowledged Henry VII as the true king of England by right of conquest, inheritance, and national choice. The following year he appointed Tomas de Torquemada grand inquisitor of Spain. Failing to unite Christendom in a crusade to halt the Turks in Europe, he succeeded in gaining custody of Prince Jem (or Djem), the brother of Bajazet II, sultan of the Ottoman Empire. By threatening to support Jem's claim to the Ottoman throne, he brought Bajazet to terms in 1489. During his pontificate the Moorish kingdom of Granada was conquered, as a result of which the pope granted to Ferdinand of Aragon and Isabella of Castile the title of *los reyes católicos*, literally "Catholic kings."

Under his government Rome and the States of the Church fell into a condition in which robbery and violence occurred daily. Though personally affable and generous, Innocent lacked the finer shades of moral discrimination, and an important aspect of his reign was the secularization of the sacred college, to which he promoted for political and personal reasons many unworthy men. This was a great barrier to the reform of the church from within before Martin Luther.

INNOCENT IX (GIOVANNI ANTONIO FACCHINETTI): b. Bologna, Italy, July 20, 1519; d. Rome, Dec. 30, 1591; r. Oct. 29-Dec. 30, 1591. He studied at Bologna and was made bishop of Nicastro in Calabria by Pius IV in 1560. In 1652 he took part in the Council of Trent. Sent as nuncio to Venice in 1566, he helped to arrange the alliance of the pope with Venice and Spain which resulted in the victory over the Turks at Lepanto in 1571. About 1572 he returned to Rome and was made a cardinal in 1583. During the illness of Gregory XIV he conducted papal affairs, and on that pontiff's death (1591) he was elected his successor. Although he wrote prolifically, his works remain in manuscript.

INNOCENT X (GIOVANNI BATTISTA PAMFILI): b. Rome, May 6, 1574; d. there, Jan. 7, 1655; r. 1644-1655. He studied law in Rome, and in 1604 became attached to the Roman Rota. After serving as nuncio to Naples (1621-1625) and to Spain (1626), he was created cardinal in 1627 but was not proclaimed as such until 1629. He

succeeded Urban VIII as pope in 1644, and his election meant a shift of papal favor from France to Spain. He confiscated the property of Antonio and Francesco Barberini (protégés of the French cardinal, Jules Mazarin), favored the Spanish clergy, and refused to recognize Portugal's independence from Spain. In the conduct of papal affairs he depended for guidance on his sister-in-law Donna Olimpia Maidalchini whose greed, ambition, and intrigues made her extremely unpopular. He condemned Jansenism (q.v.) in his bull, *Cum occasione*, in 1653. Although he led a life of piety and was personally amiable, his diffidence and indecisiveness made his reign an unfortunate one.

INNOCENT XI, BLESSED (BENEDETTO ODESCALCHI): b. Como, Italy, May 16 or 19, 1611; d. Rome, Aug. 12, 1689; r. 1676-1689. Educated by the Jesuits at Como and in jurisprudence at Rome and Naples, he became a protonotary apostolic and president of the Camera Apostolica after entering the curial service. He was made a cardinal in 1645 and was legate at Ferrara (1645-1650) and bishop of Novara (1650-1654). Esteemed for his piety and desire for reform, he was elected to succeed Clement X in 1676, despite French opposition. He came into sharp conflict with Louis XIV over the selection of bishops in France and other aspects of Gallicanism (q.v.), and Louis threatened to separate the French church from Rome. In his civil administration, Innocent strove against nepotism, abolished sinecures, closed gaming houses, and enforced measures of economy.

In ecclesiastical affairs he recalled religious orders to strict observance of their rules, and was exacting in approving candidates for the episcopate. He attempted to revive the custom of frequent communion, but Jansenist opposition postponed this until the time of Pius X (r. 1903-1914). Although Innocent had been accused of favoring quietism (q.v.), Miguel de Molinos and Pier Matteo Petrucci were condemned during his time for teaching heresy. The process of his canonization was initiated in 1692, but after some preliminary steps in 1714 and 1736 it remained in abeyance until Pius XII beatified Innocent in 1956.

INNOCENT XII (ANTONIO PIGNATELLI): b. near Spinazzola, Italy, March 13, 1615; d. Rome, Sept. 27, 1700; r. 1691-1700. He studied at Rome and was made a prelate by Urban VIII. Having served as vice legate at Urbino, as governor of Viterbo, and as nuncio at Florence, to Poland, and at Vienna, he was made a cardinal in 1681 and became archbishop of Naples in 1687. He was elected pope to succeed Alexander VIII in 1691. Innocent prohibited nepotism in the bull *Romanum decet pontificem* (1692) and was an advocate of economy in administration; his various reforms included forbidding judges to receive gifts from parties at litigation. He ended the long quarrel between Louis XIV and Rome, and received from Louis and the French bishops a retraction of the Declaration of Gallican Liberties (see GALLICANISM). However, his reign was much disturbed by doctrinal disputes such as the question of Jansenism, which he condemned. The mystical teachings of Mme. Guyon and her disciple Fénelon (François de Salignac de la Mothe-Fénelon), which resembled quietism (q.v.), led to a lengthy dispute between Celestino Sfondrati and Jacques Bénigne Bossuet. Innocent decided against Fénelon, condemning many of his beliefs, but refused to condemn Sfondrati's book on predestination.

INNOCENT XIII (MICHELANGELO CONTI): b. Rome, May 13, 1655; d. there, March 7, 1724; r. 1721-1724. Having served as nuncio in Switzerland and in Portugal, he was made a cardinal in 1706 and later became bishop of Osimo and of Viterbo. Soon after he was elected pope (1721) in succession to Clement XI, he invested Charles VI of the Holy Roman Empire with Naples. Hoping for a restoration of Roman Catholicism in England, he supported James Francis Edward Stuart (q.v.), the "Old Pretender," in his claim to the throne. He showed disfavor to the Jesuits and forbade them to receive novices in China, where they were accused of allowing the retention of certain Chinese rites. It was for a time feared by the adversaries of the Jansenists that Innocent would repeal the bull *Unigenitus* (1713) because he had, while a cardinal, spoken against its publication. However, as pope, he required its acceptance.

Bibliography.—GENERAL WORKS: Mollat, Guillaume, *Les papes d'Avignon* (Paris 1912); Mann, Horace K., *The Lives of the Popes in the Middle Ages*, 18 vols. (London 1925-32); Pecchiai, Pietro, *Roma nel Cinquecento* (Bologna 1948); Vacant, Jean Michel A., and Mangenot, Eugène, eds., *Dictionnaire de théologie catholique*, 15 vols. Professor of History, Cathedral College, New York.

INNOCENTS ABROAD, *The*, in'ô-sents à-brôd', in full *The Innocents Abroad, or The New Pilgrim's Progress, Being Some Account of the Steamship Quaker City's Pleasure Excursion to Europe and the Holy Land*, first of the major works of Mark Twain (Samuel Langhorne Clemens, q.v.), published in July 1869. Early in 1867, the author was in New York City as special correspondent for the *Alta California*, a San Francisco newspaper. Seeing the announcement of an excursion to the Mediterranean in a chartered steamer, he persuaded his employers to send him along. The resulting 50-odd letters of travel, written between June and November 1867, were the basis for the book. About half the work, including most of the second part, was taken from the newspaper with only minor revision; the rest was rewritten and expanded. Issued by the American Publishing Company of Hartford, Conn., a subscription house, the book sold about 100,000 copies in its first three years and, in its author's words, "went right on selling, just like the Bible."

When Mark Twain took the trip, he was 31 years old, had never been out of the United States, and, except for New Orleans, New York, and Philadelphia, had never seen a city more than 50 years old. Overseas he alternated between reverence and ridicule. Thus he was awe-struck at what the worn pavements of Pompeii revealed of the continuity of human life, but he mocked the old masters and fraudulent relics his fellow tourists gushed over, because he suspected the emotion was insincere. In the Holy Land, similarly, he described the squalor he saw, which the devout tended to overlook in their piety. As a result, some earnest people thought the book blasphemous.

Although, like most of Mark Twain's works, the *Innocents* is uneven, it contains enough of the perennial comedy of guileless tourism to be entertaining still.

DELANCEY FERGUSON.

INNS OF COURT, inz, kôrt, four legal societies in London which control admission to the English bar. Their names—Lincoln's Inn, the Middle Temple, the Inner Temple, and Gray's Inn—are derived from the buildings they occupy near the Royal Courts of Justice. Founded in the 13th century, the Inns of Court were successors to the London law schools which Henry III suppressed in 1234. Restrictions which prevented the clergy from teaching civil law and from appearing as advocates in civil courts had opened the legal profession to poorly qualified practitioners; to remedy this situation, Edward I in the late 13th century delegated the responsibility of training and licensing legal practitioners to groups which later became the Inns of Court. Their establishment represents the triumph of the common law and its severance from canon law and classical learning.

The societies were originally groups of students who resided at the various inns, where they studied law as apprentices to eminent legal personalities. In the 17th century they fell into decay, but the establishment in 1853 of the Council of Legal Education and the formation in 1894 of the General Council of the Bar restored their position. No longer residential, they have become centers of the profession and of legal education in England. Through their joint council they give lectures for students, hold examinations, and have a monopoly on the privilege of "calling to the bar" or conferring the rank of barrister. Law students must ordinarily spend a minimum probationary period of three years' study at one of the Inns before being called to the bar. Each of the societies disciplines its own members and in extreme circumstances may deprive a member of the right to practice. Each has its own governing body whose members are known as benchers; ordinary barristers and students make up the remaining membership. Prominent persons may be appointed honorary benchers of any of the Inns of Court, and the royal family usually has members on the benches of all four. The Inns of Chancery, lesser institutions where students prepared for the Inns of Court, ceased to function in the 19th century. See also BARRISTER.

British Information Services, New York.

INNSBRUCK, inz'bröök, Ger. ins'bröök, city, Austria, capital of the Province of Tirol, located in the eastern Alps at an altitude of 1,883 feet, on the Inn River at its junction with the Sill, about 60 miles south of Munich, Germany. Famous for the beauty of its rugged mountain scenery, the site of Innsbruck has commercial and strategic importance as well, since it is at the point where the route connecting western Europe with the Danubian plains crosses the easiest route from Germany to Italy via the Brenner Pass. A railroad and market center, it has little industrial importance, but there are food processing plants, a hydroelectric plant, and some textile mills. Since it offers mountain climbing in the summer and skiing and other sports in the winter, it is a year-round resort, and tourism is an important source of income.

The older part of the city is around the bridge across the Inn. The many imposing buildings here include the Fürstenburg, a 15th century castle noted for its Goldene Dachl (a balcony with a gilded roof) and the Hofkirche, or court church, which contains the monumental cenotaph of Emperor Maximilian I. St. Anne's Column, the Ferdinandeum Museum, the Museum of Tyrolean Folk Arts, and the botanical gardens are other points of interest. The university (founded in 1677) is the center of cultural activities.

There have been settlements on this site since prehistoric times, and there was a Roman station on the site of the modern suburb of Wilten. Innsbruck was fortified in 1233 and became the capital of the Tirol in 1420. The residence of a branch of the Habsburg family from 1363 to 1665, it was the center of the revolt of Tyrolean peasants in 1809. Pop. (1951) 95,055.

INO, ī'nō, in Greek mythology, the daughter of Cadmus and second wife of Athamas, a legendary king of Boeotia. See **ATHAMAS**.

INOCULATION. See **VACCINES AND VACCINATION**.

INONU, ē-nū-nū', **İsmet** (known until 1934 as **İsmet Paşa**, pā-shā'), Turkish statesman: b. İzmir, Turkey, Sept. 24, 1884. Educated in Turkish military schools, he was commissioned a lieutenant in 1903, and during World War I served as chief of staff for Mustafa Kemal (later known as Kemal Atatürk, q.v.). When the Greek Army invaded Turkey in 1921, İsmet led guerrilla forces to delay it and won a notable victory at the village of İnönü. At the Lausanne Conference (1922-1923) he negotiated a peace treaty with Greece and won recognition for the Turkish republic. He became the first prime minister of the new republic in 1923 when Mustafa Kemal was elected the first president, and together they began the progressive westernization of Turkey. When Turkish law (1934) required that all citizens adopt surnames, İsmet Paşa became İsmet İnönü in memory of his victory at that town. He resigned as prime minister in 1937, but after the death of Atatürk the following year, he was unanimously elected president and held that office until 1950.

An authoritarian president, though not quite a dictator, he continued the process of westernization in Turkey. In international affairs he proved himself to be an astute diplomat, skillfully preserving Turkey's neutrality throughout World War II; and he won great respect abroad by his gradual introduction of democracy in Turkey. In the late 1940's he allowed the formation of opposition parties, and in 1950 he supervised the first completely free elections in Turkish history. His People's Party was then defeated by the new Democratic Party led by Celâl Bayar.

INOUE or **INOUE**, ē-nō-ō-yē, **MARQUIS KAORU** or **KAARU**, Japanese statesman: b. Yamaguchi, Japan, Jan. 28, 1835; d. Tokyo, Sept. 1, 1915. A samurai, or lesser nobleman, of the powerful Choshu clan, he recognized the necessity of westernizing certain aspects of Japanese civilization, and in 1863 made a secret trip to England with Hirobumi Ito (q.v.). After two years of observing Western methods, he returned to Japan where he was a leader in the reform movement highly brought about the Meiji Restoration in

1868. Inoue contributed to the reorganization of government finances and served as minister of finance in three of Ito's cabinets. In addition he headed at various times the ministries of foreign affairs, internal affairs, agriculture and commerce, and in 1895 was sent to reform the government of Korea. He retired in 1898, but during the war with Russia (1904-1905) was an adviser to the finance minister. His services to the state were rewarded with the title of count in 1885 and of marquis in 1907.

INQUEST, ĩn'kwēst, in law, a body of men appointed to determine facts; also, the inquiry itself or its findings. In its broadest sense it is synonymous with the term "inquisition" and covers any judicial inquiry. In practice, however, it is restricted to certain special proceedings and should be carefully distinguished from ordinary jury proceedings, which find facts in the customary form of trial between adversaries. An inquest may be an official investigation to establish undisputed facts so as to make them a public record. It may also be an impartial inquiry which may hear evidence of multiple possibilities. The *grand inquest* is the grand jury, whose power of inquest includes the right to go further into matters before it than the evidence presented, when it sometimes is called a "runaway jury."

The *coroner's inquest*, which investigates the causes of sudden or suspicious deaths, is a typical and perhaps the most familiar kind of inquest. Here the coroner (whose office in some jurisdictions is now filled by a "medical examiner") sits as a quasi judge with a jury which determines whether a death was a murder, suicide, or the result of natural or other causes.

An inquest proceeding may determine the amount owed by a defendant who lost his suit by default. Such an inquest may be conducted by a sheriff or the court itself; in either case a jury may or may not be used. Another common inquest is that of lunacy, whereby a finding is made as to an individual's mental competence to manage his affairs. An *inquest of office* determines whether or not the government owns land by forfeiture or escheat. It was common when land was held in military tenancy direct from the crown.

JOHN M. WILLIAMS, JR.

INQUILINE, ĩn'kwī-lin, a zoological term applied to animals which are nonparasitic yet live within the homes or bodies of other animals. The term is applied to a great variety of cases ranging from insects living within the nests of other insects to fishes which live as inquilines inside the bodies of sponges. The phenomenon is closely related to commensalism (q.v.), but often it is difficult to imagine that a benefit accrues to each member of the relationship. Commonly, one species invades a part of the habitat of a closely related species, with the host species seeming not to suffer harm nor to reap any benefit from the arrangement. Much modern biological research has focused upon the mechanisms by which inquilines locate and remain within the host or the host territory.

An example is provided by the investigations of John H. Welsh at Harvard University using the mite *Unionicola*, an inquiline which lives in the gills of fresh-water mussels. Welsh found that the mites swim toward light until they encounter a chemical exudate of the mussel, at which time they exhibit a strong negative reaction to light. This causes them to turn toward the mussel and very often to swim into the mantle cavity of the host. This relation-

ship is exhibited by many mussels and mites; however, like most relationships of inquilines and their hosts, it is entirely species specific, which means that a particular species of mite is sensitive only to chemical exudates of its own host animal.

Examples of inquiline relations occur among termites, ants, and bees, and are especially known among gallflies (see GALLS).

EDWARD S. HODGSON,
Assistant Professor of Zoology, Barnard College.

INQUISITION, The. In ancient Roman Law, and in the Papal Canon Law which grew up from it, two forms of criminal procedure were recognised, the Accusatorial and Inquisitorial. The former is familiar to us all; a definite prosecutor called into court a definite defendant, and sought to prove his case by ordinary forms of testimony and pleading. The second, however, needs explanation. Under this procedure, a great part was played by *fama*; that is, by *report*, not in the loose sense of "common rumour," but as the testimony of two or three knowledgeable and trustworthy witnesses. When such a *fama* reached the ears of judicial authorities, then the man was *infamatus* (or *diffamatus*) of the offenses in question. The judge then became his accuser: "You are *diffamatus* of such and such an offence: therefore you must appear before me and clear yourself on oath, and if possible by the oath also of a specified number of competent witnesses." Thus an inquiry (*Inquisitio*) is set up; and, whereas under *Accusatio* the burden of proof would have rested upon the prosecutor, it is now laid upon the defendant. To grasp this clearly is to understand, from the very first, why the medieval Inquisition never struck full root in England, where the Common Law was a natural growth of English life, "broadening down from precedent to precedent."

It was equally natural that inquisitorial procedure came to be generally and intimately associated with questions of religious belief.

Here again, we cannot understand the Middle Ages so long as we ignore the eschatology of that period: men's current convictions in the matter of Heaven and Hell. During more than a thousand years, the orthodox belief was one of almost inconceivable severity. Hell was conceived as a place of torment infinite in duration, and indescribable in its horror. Moreover, it was assumed that the great majority of mankind were destined to this eternal torment. St. Thomas Aquinas, quite as a matter of course, contrasts the "few" of the saved with the "multitude" of damned. St. Bernardino (d. 1444), from whom as a Franciscan we might expect special human sympathy, even taught that the Harmony of the Universe necessarily demanded this contrast; that the Music of the Spheres would have been imperfect but for the bass part supplied by the howling of the guilty multitude.

These ideas had reigned from time immemorial, and the most unforgivable of all delinquencies was deathbed impenitence: *Extra Ecclesiam nulla salus*. In such an atmosphere as this, the most horrible social crime was that which dragged down to Hell not only the heretic himself, but perhaps thousands of perverts with him. Therefore Pope Innocent III, in 1199, formally condemned heresy as the most unpardonable of treasons, "since it is far more grievous to sin against the eternal than against an earthly Majesty." This memorable decree laid the foundation of the Inquisition as an institution unprecedented

in world history. It was upon this basis that St. Thomas Aquinas bent his genius to build the theory which his faithful followers have held down to the present day. "If false coiners or other felons are justly committed to death without delay by worldly princes, much more may heretics, from the moment that they are convicted, be not only excommunicated, but slain justly out of hand." (*Summa Theologica*, 2^a 2^{ae}, Quest. xi, art. iii).

The Roman Church—*Ecclesia Romana* as it was commonly called in the Middle Ages—claimed then, and has never since renounced, the philosophical title of *Societas Perfecta*: a state in its own right, with powers of legislation over all its subjects and the sanction of punishment over the disobedient, even to the extreme penalty of death. It claims that its subjects are all men or women who have received Christian baptism, whether deliberately or as infants at the font.

For the claims of the state in matters of conscience, see Bishop Creighton in his *Persecution and Tolerance* (1895). The early Christians had differed much from each other; nearly a hundred sects developed in the first hundred years. In some cases there were mortal enmities; in others we find remarkable tolerance, as when Justin Martyr, the earliest surviving apologist (160 A.D.) condemns only those who reject the faith with contumely, and honors with the title of Christian such pagan philosophers as Socrates and Heraclitus, since they lived for the truth, and Christ is Truth. In a later generation (200 A.D.) Tertullian gloated over the hell-pains awaiting pagan torturers, in a passage rendered notorious by Gibbon and Lecky; but this was when the unpopular sect had been embittered by persecutions. Presently, the tables were reversed, and Christianity was victorious under Constantine I.

In the great domestic quarrel provoked by Arius (325 A.D.), the emperor finally sided with the majority of bishops. He banished the heresiarch, commanded under pain of death that all his books should be surrendered, and sent him into exile with the two bishops who still maintained his cause. From that time forward the state made itself responsible for government in the church. Heretical priests were punished. Paganism was condemned as a *superstitio*, and the pagan temples were disestablished and plundered with even greater thoroughness than Henry VIII showed in the England of 1530.

In 381, the Emperor Theodosius set his seal to a series of enactments which punished heresy. In 385, the heretic Priscillian was executed by the Emperor Maximus, despite the protests of St. Martin of Tours. A generation later St. Augustine, who at first had pleaded for tolerance of the Donatists, emphatically revoked this in course of time, appealing to what seemed practical experience, since confiscation of property and other similar penalties are efficacious in calling men's attention to the orthodox faith. A generation later (438) Theodosius II published his celebrated *Code of Roman Law*, in which, *inter alia*, are severe laws against pagans and heretics, thus giving the Church the status of a *Societas Perfecta*, with legislative and punitive powers.

There was now a lull in religious manslaughter; Europe was too troubled, and too barbarous, for any important anti-clerical movement to come into collision with the hierarchy. But, all this while, there was gradual infiltration of organised heresy from the East. The Manichaean creed had

just enough in common with Christianity to be a dangerous rival. St. Augustine himself had been a Manichaean in early life, and had found the heretics formidable enemies in his African bishopric. The gloom of the Dark Ages (6th to 11th century) from which very few intimate social records have survived, doubtless hides much underground nonconformity. But when we come to that religious and intellectual revival which deserves to be called the Renaissance of the 11th century, we suddenly find heresy very much alive. The chronicler, Ralph Glaber, a Cluniac monk, tells us how, around the fateful year 1000, "it seemed as if the world shook itself and cast off its hoary age, and clad itself everywhere in a white robe of Churches." Yet this light fell upon a barbarous world.

"It is horrible to relate what corruptions then prevailed among men." There were plagues and famine and cannibalism among the multitude; and in the Church itself, Glaber stigmatises the debaucheries of one pope (Benedict IX) as "too horrible to relate," while he accuses the whole clergy as demoralized by greed, and infected from the head with the mortal sin of simony. In such a world as this he describes four pestilent outbreaks of heresy in the most civilized parts of Western Europe; and from this time forward the chain is complete, down to the Renaissance and Reformation. We find four fairly definite periods: Lynch Law, Civil War, Episcopal Inquisition, and Papal Inquisition.

The "white robe of Churches" came in a period of Lynch Law. The lay authorities, as a whole, were definitely hostile to the innovators, and the multitude could be raised against them. Here and there, a bishop or priest can be found more merciful than the mob, but this is very rare, and we may apply the legal maxim: *Fecit qui profuit* (He did the deed who profited by it). For to the clergy this was a matter of life and death. Religious changes involve social revolution, and heresy threatens violence and plunder. The totalitarian claims of Rome, while on one hand they gave her increased power, rendered her otherwise vulnerable in many directions. Thus, during the 11th century, both sides mobilized their forces, and, by 1100, all tended to civil war. It was a time of rapid advance in the arts of peace and civilization. The monastic orders grew apace; the hierarchy and the feudal nobility were better organized and disciplined, and it became increasingly impossible to drift onwards on a system of Lynch Law and guerrilla warfare. Orthodoxy and Heterodoxy mobilized their respective forces; until, at last, in the 12th century, came civil war on a great scale.

On the eve of this explosion, we have a most significant sidelight from the Rhineland, which shared with northern Italy and southern France the credit of greatest advance in civilization. This is an exchange of letters between Erwin, Prior of Steinbach near Cologne, and Bernard, who stands beside St. Francis among the greatest of canonized saints. He was learned, eloquent almost beyond all of his age, and fearless in his dealings with popes and princes: Pope Eugenius III had been one of his pupils. About 1130 A.D. he had made a special missionary journey among the heretics of southern France, the land of the Troubadours. Here the saint, confessedly, met with little success. Erwin now wrote describing his own difficulties with organized heresy in the Rhineland. The folk described by Erwin answer to those Beg-

hards, Béguins, Béguines who, after long hesitation on the verge of revolt, finally plunged or were thrust into the abyss, and were in the 13th century identified or confused by Bernard Gui with "spiritual" Franciscans. Here, under Erwin's pen, they appear far more nearly akin to the later Vaudois. The good prior found them attractive; and therein lay the difficulty. Their lives seemed blameless; and these unbelievers boldly challenged the multitude of believers with Christ's criterion: "By their fruits ye shall know them."

That was a mystery for St. Bernard also; he had often deplored that his Church set a bad moral example; she was preyed upon by a cancer, and the remedies seemed only to make her worse. He was constrained now to admit the apparent regularity of these men's lives, and even their frequent semblance of piety. The heretic "is pale with fastings; he eats no bread of idleness; he works with his hands for his livelihood, where then is the fox?" It lies in their contempt of Church authority: they "give holy things to the dogs." They are "a vile and rustic crew, unlettered and altogether unwarlike." Even their righteousness is but as filthy rags; "they do indeed abstain, but they abstain heretically." These words are typical of the spirit which inspired orthodoxy in those days.

St. Bernard is often quoted as an apostle of tolerance, in something like the modern sense; men quote his words: "Faith is a matter of persuasion, not of force." But we must read on for a few lines and we shall find how in his succeeding words he very plainly appeals for the punishment of persistent heretics. (In *Cant. sermo* LXIV. c. 12.) The hierarchy was puzzled; popes and councils had no clear-cut policy. It is not until 1209 that we find a council definitely basing itself upon the plain claim of "Death for the Heretics" as a maxim both of Canon Law and of State Law. Thenceforward, this lies at the very foundation of medieval European society. Meanwhile, things were steadily drifting towards civil war, which broke out in 1195.

Southern France, Languedoc, was more advanced even than the Rhineland. It had a social system far older than the North. It was less warlike, more mercantile, more luxurious, and less papalistic. Jews flourished there, and society was strikingly tolerant of religious differences. In consequence, it had become a favorable ground for the spread of Manichaean doctrines which had filtered in from the East. Recent scholars have doubted whether these Provençal heretics held the creed with Eastern exactness, but there is no doubt of their main features. They held a dualism, an equilibrium between good and evil, God and Satan, which shall endure until the end of all things. Meanwhile, there is perpetual conflict between Light and Darkness, Mind and Matter. The flesh is evil; therefore, true religion is strictly ascetic. Sexual commerce is sinful, even in matrimony. Diet must be vegetarian, rejecting even eggs and everything that has had life, with an illogical exception for fish. Those strict rules, however, were binding only upon the *perfecti*: the multitude, *credentes*, seem in practice to have differed little more from orthodoxy than did the Quakers of the first generations. The whole sect called themselves *Cathari*, "the Pure." They had a hierarchy of their own, with rites and sacraments partly imitated, perhaps, from the Church, but more probably derived from those same sources of Imperial Rome from which the priesthood had

borrowed so freely. They reprobated bloodshed and swearing and set up against the Catholic extreme unction a ceremony which pushed to extremes that fundamental repudiation of the flesh. It was called *Endura*, a religious suicide by starvation or a wet napkin spread over the face on the deathbed.

Jules Michelet (followed by H. C. Lea and Abbé E. Vacandard) judges that it would have been disastrous to civilization if the *Cathari* had conquered in the civil war of Languedoc. But was there any valid reason to anticipate such a victory? The *Endura* itself it not immeasurably more barbarous than some forms of asceticism which orthodoxy has admired; and there is no probability that these *Perfecti* would have destroyed throughout Europe the immemorial institution of marriage, and would have thus involved wholesale race-suicide, as even such a moderate churchman as Vacandard argues. Is it credible that, if St. Bernard had been consistent in leaving the decision to "persuasion, not arms" any more would have been done to depopulate the world than had been already done by a thousand years of monastic celibacy? Swearing, again, is often cited as a crucial point. The structure of medieval society, it is argued, was fundamentally feudal: its elaborate network of legal and customary obligations reposed upon the multiple oaths of fealty, taken publicly on the Gospels, at every turn. But would European culture actually have been wrecked by the obligation to find gradually some firmer basis?

Great churchmen of the Middle Ages complained constantly that this flood of oaths debased the moral currency. No doubt the heretical tenets implied social as well as religious revolution; but it is quite mistaken to represent the men as mere anarchists. Abbé Vacandard condemns severely those modern apologists who press this argument, in flat contradiction with the records. He writes: "As a matter of fact, the Inquisition did not condemn merely those heresies which caused social upheaval, but all heresies as such." In fact, he points out, men were often prosecuted after their death—even 20 or 30 years later. Why should Inquisitors take all this trouble with men whom God had already judged, and who could do no further harm to society? Because, as Vacandard points out, this "almost incredible frequency of prosecutions against the dead" went to fill the coffers of the Inquisition.

The Inquisitor Eyméric, one of our best original authorities, confesses with brutal frankness that the Inquisition of the day (1360) languishes because nearly all the wealthy heretics have been condemned, and this Holy Institution must live upon its scanty pickings from the poor. Thus Catharism and Waldensianism on the Continent, like Lollardy in England, were driven underground. Those three heresies by this time were hammered into some similarity by common sufferings of persecution.

The Waldensians, or Vaudois, were a sort of Bible-Christians founded about 1180 by Peter Waldo, a rich merchant of Lyons, who gave his money to the poor and embarked upon a missionary career founded upon the translation and popular exposition of Scripture in the native tongue. He began as peaceably as John Wesley, but was driven to separation from this totalitarian world which had no room for rival religious organizations. One of Macaulay's most often-quoted sayings is only superficially true—that Rome, unlike

other churches, has succeeded in utilizing religious enthusiasm and keeping the mystic within her bosom. Darwin, when he lived in a country of fir-woods, wondered that the meadows were not full of self-sown firs. It was only by degrees that he realized that thousands of such seedlings were all the time around him, remorselessly cropped by the cattle or the mowers before they had grown recognizable. Microscopic observation of the Middle Ages shows us a similar process among the seedlings of religious nonconformity. The heretics were often, as St. Bernard describes them, obscure and unwarlike. They showed that astounding tenacity of memory which has often been observed in illiterate folk. More than one Inquisitor testifies to their enormous superiority in this field over the parish clergy. Sacconi writes in about 1250: "I have heard and seen a certain ignorant rustic who recited Job, word for word, and many who knew perfectly the whole New Testament." He contrasts this with the "negligence of Catholic teachers." These men, therefore, were most formidable antagonists in an age when books were so few and dear that a Bible cost more than the whole yearly income of an ordinary parish priest.

Bernard Gui (1300) warns Inquisitors that "it is not expedient to dispute concerning the Faith against such astute heretics in the presence of lay-folk." St. Louis, in many ways a most noble character, warned his knights against disputing with an unbeliever; let him rather "thrust his sword into the man's belly, as far as it will go." In about 1230, a certain weaver at Toulouse would say publicly: "lords, hear me! I am no heretic, for I have a wife, and lie with her and beget children, and I eat flesh and lie and swear, and am a faithful Christian." In 1247, another Toulousan, Pierre Garcias, burst out: "If I could lay hold on that god who, out of a thousand men whom he had made, should save one and doom all the rest, I would tear and rend him tooth and nail as a traitor, and would count him as a false traitor and spit in his face."

When the civil war was thoroughly kindled there was little to choose between the combatants in frenzy of conviction or brutality of methods. The Catholics at one moment tore out their prisoners' eyes and cut off their noses, claiming just right of reprisals. When the Catharist city of Béziers was stormed (1209) by Simon de Montfort's Crusaders, Innocent's cardinal legate reported to the pope that "our men, sparing neither rank nor sex nor age, slew about 20,000 souls" and pillaged the whole city. The contemporary papal chronicle puts it more tersely: "almost all were slain." Innocent, without a word to hint that his Crusaders had done more than their strict duty, wrote now to congratulate them on the remission of past sins and the accession of worldly wealth which they will have earned through their obedience to the vicar of Christ.

It is sometimes urged that the procedure of the Inquisition is not unique: that each separate item can be paralleled from elsewhere. Even though this were true, it would not exonerate the inventors of this particular compound; gunpowder has its own peculiar character and peculiar effects even though sulphur, charcoal, and saltpetre, taken separately, behave very differently. But the excuse itself is fundamentally false. It is contradicted by the best of contemporary lawyers, Bernard Gui, whose *Inquisitor's Manual* has been published, in its most important section, by Messrs.

Champion of Paris at a popular price, with French translation. Bernard writes clearly that *Multa sunt specialia* in Inquisitorial procedure. He specifies a concrete instance: whereas other courts demanded a minimum of two witnesses against the suspect, the Inquisition often acted upon a single testimony. Its main characteristics were, briefly, as follows:

(1) The fundamental bias has already been described, the man was *defamatus*, and bore the burden of proving his innocence.

(2) His judges were purely ecclesiastical, and therefore prejudiced against him: the civil power strove vainly to secure even the right of consulting the documents.

(3) The procedure was secret.

(4) As a rule, the names of witnesses were also concealed; they might be partial or even infamous persons, yet the suspect had no chance of challenging them but at random.

(5) In fact, infamous persons were explicitly admitted to testify though in other courts their testimony was altogether refused.

(6) So, again, children were admitted to testify adversely, whereas neither the infamous person nor the child might speak in defence.

(7) Advocates were at first allowed, but if the person was proved guilty, the advocate had to share his punishment; this was so shamelessly exploited that, finally, even the pretense of advocates for the defense was abandoned.

(8) It was equally hopeless to rely upon favorable witnesses; for they were pretty sure to get into trouble as abettors of heresy.

(9) Torture might be inflicted not only on the suspect, but also upon any witnesses whom it was hoped to enlist for the prosecution.

(10) This had, in practice, no legal limits. It was indeed forbidden to *repeat* torture; but the man who had been racked on Monday might be racked again on Tuesday under the excuse of *continuation*.

(11) A very small nonconformity might be magnified into a deadly crime.

(12) The medieval Inquisitor pushed in where the pagan of ancient Rome had disdained to tread. When Trajan commissioned Pliny to persecute, he forbade the seeking-out of secret Christians. Yet the medieval heretic had no such immunity. Every man was bound in strict conscience to spy upon and denounce his neighbor.

(13) There were other rigors, of which the result is that an acquittal, pure and simple, is almost unheard of in these records. Very seldom was there less punishment than the yellow Crosses of Infamy, about a foot long, to be worn night and day upon every garment but the shirt, which held the victim up to the mockery of the multitude.

In Bernard Gui's *Register* (between 1249 and 1258), among 200 suspects, there is not a single acquittal. In his whole lifetime he convicted 930, of whom 42 were burned. Of the rest, 307 were condemned to prison; and all 930 were liable to total confiscation of their goods.

A word must be added concerning those two items, prison and confiscation. The former was frequently used as a most serviceable weapon in the war of nerves. "Confess, or you shall go to prison," was generally effective with men who knew very well what sort of dungeon this was. As to confiscation, it will be seen how far this went to supply the sinews of war.

One most important point must be noted be-

cause it is so frequently alleged by apologists. The Church, it is argued, explicitly repudiates the shedding of blood; she only condemned the heretic as a theological question undoubtedly within her competence. Then she handed on the condemned man to the civil power, "the Secular Arm." The latter, however, had no option but to burn him. Any magistrate who refused would himself be liable to be burned alive. So the hierarchy could preach "*Ecclesia abhorret a sanguine*." "Let us call it a legal fiction," writes Abbé Vacandard apologetically. Most people probably will give it a more invidious name.

Here then, was a lethal weapon, an invention as elaborate and as devastating in its own way, as gunpowder. It was inevitable that despotism should seize upon it as a ready tool. Even its spectacular sides, its cross of infamy and campaigns of blood and flame, were not so deeply operative as the leaden pressure, ubiquitous and unrelaxing of centuries of tyranny. History shows us this, in the rule of the Arian anti-Catholic invaders of Africa, and in the far milder, but still very regrettable, rule of Elizabeth in England and in Ireland.

From the year 1239 onwards, most Europeans lived under a terror which was not less harmful for being so often unconscious. England, it is true, with her greater political freedom than the Continent, suffered only twice from the Inquisition proper. In 1311, Philippe-le-Bel of France, with Pope Clement V as his uneasy partner, used it as a tool for disreputable political ends: the destruction and pillage of the Templars. The unscrupulous use of torture in France, produced a series of confessions which nobody believes now, and which, indeed, were often revoked by the victims themselves outside the torture-chamber. In England, no cogent evidence could be found, because the English courts permitted no torture. Therefore Clement approached Edward II with a bribe and a threat: Obey, and we give you plenary absolution for past sins; disobey, and you fall under excommunication. Edward yielded "out of reverence for the Holy See," and enough evidence was scraped together to justify the desired confiscation and pillage. During Mary's reign, again, the Inquisition was revived in England for a few months.

There are three other outstanding instances of the Inquisition used as a political weapon in the Middle Ages. In 1318, Pope John XXII let it loose upon the "Spiritual" Franciscans, so that his Inquisitors condemned and burned, as impenitent heretics, four men whose recorded offenses amounted only to this, that they clung obstinately to the primitive simplicity of Franciscan garb and manners, even in face of the pope and the Franciscan officialdom of that day. Again, in 1430, Joan of Arc was condemned for witchcraft (her real crime being her noble patriotism) by a judge who was a tool of the English conquerors. It was not until our own days that she was formally sainted by her own church. Once more, in 1498, the friar Savonarola was burned for his political and social opposition to the Medici family and the notorious Pope Alexander VI. He was put seven times to torture with slender results. "It would be easy," writes Abbé Vacandard, "to cite many instances of the same kind, especially in Spain."

The Inquisition in Spain.—Medieval Spain was almost equally divided between three religions—Christian, Moslem and Hebrew. Paradoxically, this led on the whole to tolerance, since none of

the three saw any proximate chance of "liquidating" completely the other two. There were occasional resorts to formal Inquisitorial methods, and sometimes anti-Semitic explosions even on an extensive scale, and the Moslem population formed standing political difficulties; but these were mostly dealt with on the *solvitur ambulando* principle. Jews and Moslems arrived at some of the highest positions in State and even in Church; and on all hands the quiet infiltration was enormous. This very fact of Semitic ascendancy largely motivated the great anti-Semitic movement of the 15th century, in which many thousands of Moslems and Jews had no choice but between "conversion" and death, and where St. Vincent Ferrer, for instance, is recorded by his partisans to have baptized four thousand in a single day. Hence came a dizzy multiplication of "New Christians" (*conversos*, popularly labeled *Marranos*, swine) who dominated the laboring and professional classes of Spain. Pogroms became frequent; and here, as elsewhere at earlier dates, the Inquisition substituted some sort of legal regularity for mere lynch-law.

Queen Isabella of Castile, "The Catholic," obtained the formal foundation of the Inquisition from Pope Sixtus IV. It began operations in 1480; her husband, "Ferdinand the Catholic," joined her whole-heartedly; and gradually the institution struck root throughout the peninsula. Sixtus did indeed send another bull severely criticizing its methods; but his objections were ignored. The two sovereigns, from the first, used it as the foundation of their political despotism. Thenceforward, from century to century until 1834, it was the most characteristic of Spanish institutions.

Its methods were medieval, "writ large." Church and State were here in complete fundamental accord; kings and popes might quarrel over details, but those were the quarrels of lovers. An able Roman Catholic writes very truly: "No church could be more arrogantly national than the Spanish, fenced around as it was with exemptions, royal, episcopal, monastic. But none was ever more Catholic. It bred neither heresy nor schism." Confiscations, beyond even the medieval scale, ensured enormous revenues which supported both royal splendor and the Roman religion to an extent never surpassed in history. In the 16th century, when Spain gathered also immense revenues in bullion from the New World, she bade fair to dominate Europe. That was her Golden Age in literature and art, the age of Cervantes and Velasquez. But this was at the cost of a royal and aristocratic extravagance, of an unabashed financial corruption, and of a burden upon the working classes, which have seldom been equaled for so long and on so large a scale.

Inquisitorial statistics have often been handled in irresponsible fashion; in most cases of wide divergence it is safe to take the lower figures. At the first *Auto de Fé* (Seville, 1481), six persons (men and women) were burned. Within the next eight months, 292 more were burned, 98 imprisoned for life; many more were torn from their graves in order to justify confiscation of their property. Under Tomás de Torquemada (q.v.) the tempo rose considerably. He was appointed Grand Inquisitor in 1483, making this institution "the first act of United Spain." Under Philip II (1569) the principles of the Inquisition were transplanted to Mexico, where 879

trials took place in the next quarter of a century. Meanwhile, the revolt of the Low Countries, costing a murderous war before Belgium was brought to heel and Holland finally severed from Spain, must be put down mainly to the score of the Inquisition. In Portugal a little later (1651-1673) the records show 184 burned alive, 59 burned in effigy with confiscation, and 4,793 penanced. As many as 1,500 "penitents" were paraded on one single occasion.

Within those postulates of Spanish political thought, it was only logical to carry out persecutions or deportations of Jews and Moors, sometimes piecemeal or again on an enormous scale. The Jews were banished by law in 1492, from which time onwards the country was filled with Jewish *Marranos*. Those who remained constantly fed the *Autos de Fé*, while those who escaped enriched the commercial and cultural life of other countries: everywhere they founded respected communities, as in Amsterdam, Hamburg, London and New York. The *Moriscos*, on the other hand, finally added to their minor and continual political sufferings one of the most picturesque tragedies of all time, the mass-deportation of the whole Moorish population, insofar as such completeness was fully possible, between 1609 and 1615. The few who remained were strictly forbidden all use of their ancient language and customs. National life was thus impoverished by the loss of its most laborious factor. By a strange irony of history, the most recent victory of physical force in Spain was won by an orthodox general (Francisco Franco) commanding an enormous proportion of Moorish soldiers, and foreign mercenaries.

The 18th century showed gradual decay of the Inquisition, but only in proportion to the decay of the whole country, which is calculated to have lost 50 per cent of its population since the days of Ferdinand and Isabella. In 1808 Napoleon abolished it, and its resurrection lasted only until 1834. But there remained an incalculable debt for past errors and crimes. The Comte de Montalembert, a fervent Catholic, contrasted the racial virtues of Spain with her political and social decadence in 1800: "She has fallen from gulf to gulf, from despot to despot, from favorite to favorite."

Modern apologists avoid dealing with the reluctant confessions of many among the most eminent Roman Catholic historians. Cardinal Richelieu, a realistic statesman who shrank from few deeds that his policy demanded, described the expulsion of the *Moriscos*, in his *Memoirs*, as "the boldest and most barbarous counsel recorded in the history of all preceding ages." Montalembert wrote "I grant indeed that the Inquisition in Spain destroyed Protestantism in its germ; but I defy anyone to prove that it has not given it throughout Europe the support of public opinion and the sympathies of outraged humanity. It has created in both worlds inexhaustible nourishment for impiety, and for the hatred and discredit of Catholicism." Lord Acton, his contemporary and a far greater historian, was even more emphatic. "The Inquisition is peculiarly the weapon and peculiarly the work of the Popes . . . No other institution, no doctrine, no ceremony is so distinctly the individual creation of the Papacy, except the Dispensing Power. . . . It was the negation not only of religious liberty, which is the mainspring of civil, but equally of civil liberty, because a government armed with the machinery of the Inquisition is necessarily absolute."

Bibliography.—Very valuable, as enabling readers to study the documentary evidence at first hand, is Bernard Gui (Bernardus Guidonis), *Manuel de l'inquisiteur*, ed. and tr. by Guillaume Mollat with Georges Drioux, 2 vols. (Paris 1926-27). The best handy volume is Elphège Vacandard's *The Inquisition. A Critical and Historical Study of the Coercive Power of the Church*, tr. from the 2d French ed. by Bertrand L. Conway (New York 1908; reprint, New York 1940). Vacandard's work is valuable for the views of a learned Roman Catholic priest, who acknowledges his obligations to Henry Charles Lea, but criticizes him sometimes freely. Equally useful and more comprehensive is Arthur Stanley Turberville's *Medieval Heresy and the Inquisition* (London 1920). By far the most comprehensive and valuable (despite serious lapses and shortcomings) is Henry Charles Lea's *History of the Inquisition of the Middle Ages*, 3 vols. (New York 1888; reprint, New York 1955). For Spain, consult Cecil Roth's *Spanish Inquisition* (London 1937). Also consult George G. Coulton's *Inquisition and Liberty* (London 1938).

GEORGE GORDON COULTON,
Author of "Five Centuries of Religion"; late
Lecturer in Ecclesiastical History, Trinity
College, Cambridge.

INQUISITIVE WOMEN, in-kwiz'i-tiv (LE DONNE CURIOSÉ), an opera in three acts by Ermanno Wolf-Ferrari (libretto adapted by Luigi Sugana from a Carlo Goldoni comedy) first produced in Munich in 1903. The first dramatic work of the composer to secure more than local notice, this opera, or "musical comedy," as he terms it, quickly achieved worldwide success by reason of its vivacity and delicate charm. Of German and Italian parentage, Wolf-Ferrari was an eclectic. The artistic lineage of *Le donne curiose* is plainly traceable to Mozart, though both *Meistersinger* and *Falstaff* influences are apparent. The orchestra, effectively used, is relatively a small one and in some respects the treatment harks back to an earlier day, when leading motives were less known. The music is distinguished by lyric simplicity and rhythmical variety. The prevailing character is improvisational, well adapted to the slight tale of harmless intrigue which it accompanies. There are several easily recognized numbers—the trios in the first act, the quartet in the second, Rosaura's love soliloquy and the succeeding pages of almost Mozartean simplicity, the prelude to the last act, the barcarolle chorus, and the final ensemble. There is no great emotional intensity, nor intellectual depth, but means and end are fitted in a thoroughly artistic and satisfying way.

LEWIS M. ISAACS.

I.N.R.I., the letters often graven on a scroll set upon the Crucifix above the head of Jesus. They are the first letters of the Latin words *Iesus Nazarenus Rex Iudaeorum* (Jesus of Nazareth, King of the Jews), the superscription ordered by Pontius Pilate to be placed upon the cross on Calvary (John 19:19).

INSANITY, in-săn'i-ti, in law, the condition of mind which places the person so afflicted in a position of being held not responsible for his conduct or incapable of attending to his own affairs. In practice, *incompetency* is often used to refer to the latter condition, and insanity is confined to matters having a criminal context. The facts are establishable by a jury in an ordinary case, although inquests or commissions are frequently used in the United States where the question is one of incompetency. Such mental conditions can be the subject of expert (opinion) testimony.

Psychiatrists complain that attorneys and

judges speak as if insanity were a specific disease. Actually, it is a legal status, attained by many different medical routes. It is probably true that over the years, attorneys and judges have garbled medical and legal principles alike. But the law must be common to, and acceptable to, all of the people; and although the law reads that a man guilty of a criminal act will not be punished if he was insane at the time of the act nor prosecuted if he has since become insane, opinion today is still clouded as to the purpose of criminal laws—whether they are to protect society, to punish, or to avenge. Thus, when some violent, gruesome crime occurs, as when a child has been sexually molested and murdered, the climate of society may demand that punishment be by execution rather than by incarceration, so that the child will be avenged and future recurrences will be impossible. To accomplish these purposes, the accused must be found sane enough to stand trial, and to have been sane at the time of the act.

The question of responsibility concerns the law more immediately than the type of distress which caused the legal irresponsibility. Thus the test of the law is not, "Is this man a paranoid or suffering from paresis?" but "Did this man know right from wrong?" Another test of the law is whether a person who knows that the act is wrong, but does it anyway, may be said to have acted compulsively, the so-called "irresistible impulse." This allows the law, through the jury as a composite conscience, the chance to be merciful in such cases as crimes of passion or murders of defective children, despite the possible medical inaccuracies involved. If the public wishes to assume the economic burden of treatment rather than of mere incarceration, the law may be able to take a different approach.

The law has a long history of tests to show insanity. After the tribal laws—such as the *manios* of the Greeks and the group *insaniens* of the Romans—and the feudal theocratic views of insanity, came a number of men and trials which evolved the tests basically used still: Thomas Erskine's successful defense of James Hadfield's attempted assassination of George III in 1800; the M'Naghten rules (of right and wrong) in 1843, adopted in the United States in *Commonwealth v. Rogers* (which also used the "irresistible impulse" rule) in 1844; and such earlier writers as Sir Matthew Hale (1609-1676) and Sir William Blackstone (1723-1780). There have also been used from time to time such tests as the wild beast test, the child of 14 test, and other concepts. A case (1956) in the District of Columbia, *United States v. Durham*, refined the statement of these rules to hold an accused not liable "if his unlawful act was the product of mental disease or mental defect."

Even more intricate and difficult matters are involved in judging those who have been called the "not-quite-incompetent incompetents," since on these judgments rests the validity of such things as contracts and wills. In most competency cases, dramatic conflicts of testimony are relatively infrequent, but the requirement of a medical opinion gives a seal of scientific authority to the proceedings necessary to confine a person to an institution or to seize his property for its conservation.

The law has been grappling with these problems for many years, and recognized early the basic questions involved. The legal tests employed have achieved a sort of empirical basis; and it seems probable that this pragmatic ap-

proach will continue unless, or until, the medical profession makes enough progress to relieve the law of this responsibility.

JOHN M. WILLIAMS, JR.

INSCRIPTIONS, *in-skrīp'shūnz*, a term comprising, in its widest sense, all words or word-signs engraved (or painted) on relatively durable materials, such as cliffs, wrought stone, baked clay, metal, or even wood. For reasons of practical convenience, however, certain sorts of inscriptions are grouped apart; for example, legends on coins and the lettering on painted vases. The role of inscriptions in modern times accords in general with the ancient use, but is much less extended; in antiquity, for example, copies of official and religious documents were frequently promulgated in the form of inscriptions. Commemorative and titular inscriptions, however, are still plentifully employed.

INSECTICIDE, *in-sēk'tī-sīd*, defined by the Congress of the United States (36 Stat. 331) as "any substance or mixture of substances intended to be used for preventing, destroying, repelling, or mitigating any insects which may infest vegetation, man or other animals, or households, or be present in any environment whatsoever." Insecticides may be classified by their mode of action or by their chemical composition.

Terms like "stomach insecticide" and "contact insecticide" indicate the way the insecticide enters the body of the insect. A stomach insecticide is eaten and swallowed. A contact insecticide enters through the cuticle. The terms have no significance as to how or where the materials exert their effect. Some substances can enter in only one way; others reach the vital organs in both ways.

Chemically, insecticides may be divided into two broad classes—inorganic and organic insecticides.

Inorganic Insecticides.—These are of mineral origin, the arsenicals being the most important group. Acid lead arsenate, made by combining litharge and arsenic acid, is used to control chewing insects on fruits, such as apples and pears, on flowers, trees, and shrubs, and on vegetables, such as potatoes and tomatoes. It also has some use in treating soil to control Japanese beetle and Asiatic garden beetle larvae and related soil-infesting forms. Calcium arsenate, sold commercially, is not a single compound but a complex mixture of several calcium arsenates and an excess of calcium hydroxide. The product is made from arsenic trioxide by first oxidizing it to arsenic pentoxide with nitric acid and then allowing the solution to react with a slurry of calcium hydroxide. The conditions of temperature, concentration, and duration of reaction are important because of their influence on the physical nature of the product. Commercial calcium arsenate generally is colored pink and is alkaline in reaction. It has been used extensively against certain insects affecting field crops, especially cotton; but it cannot be used safely on apples, peaches, beans, and some other crops because of its burning effect on

foliage and fruit. Paris green, arsenic trioxide, also called white arsenic, magnesium arsenate, sodium arsenite, manganese arsenate, and zinc arsenate also have long been used to control insects. Paris green was extensively employed to control mosquito larvae but has been largely displaced by the new organic insecticides. It is still used by home gardeners and also by commercial growers of potatoes. Antimony, an element closely related to arsenic, is used in the form of tartar emetic in poisons and for combating certain species of thrips.

Certain compounds of fluorine are also employed as insecticides. Sodium fluoride is an excellent roach powder and is also effective against lice on chickens. Sodium fluosilicate may be used in place of arsenic in poison baits for grasshoppers and the European earwig, and it is also a good roach control. The more soluble fluosilicates, such as those of zinc, magnesium, and ammonium, are used in aqueous solution to mothproof woolen goods, as are also the fluosilicates of ethylenediamine and certain other organic bases. Cryolite (sodium fluoaluminate) has proved effective for the control of codling moth larvae in the Pacific Northwest. It has also been applied to tobacco and other crops for the control of chewing insects.

Yellow phosphorus, in the form of a paste containing 1 or 2 per cent of this element, is very effective against rodents and the American roach. Mercuric chloride, although dangerous to man, has been used in ant poisons and for destroying thrips on gladiolus bulbs and for the cabbage maggot and angleworms. Mercurous chloride is also useful for the control of the cabbage maggot. Copper in the form of the basic sulphate present in Bordeaux mixture has some repellent value against flea beetles and is a specific for leafhoppers on potatoes and beans, but its principal use is as a fungicide on potatoes and apples.

Elemental sulphur is a valuable insecticide and fungicide. Large quantities are used in the form of a fine dust to which a small amount of calcium phosphate, magnesium carbonate, or other conditioner is usually added to prevent caking and ensure free flowing through a dusting machine. These dusts are applied to combat the citrus thrips in California, fleahoppers on cotton, and the potato leafhopper on beans, as well as spider mites. Powdered sulphur is also mixed with derris, pyrethrum, Paris green, and other materials for use against many species of insects. Wettable sulphurs, prepared by grinding sulphur with a gum and sodium silicate or with certain wetting agents, are similarly used as sprays. Lime-sulphur solution is used against scale insects on fruit trees and the potato psyllid, and also as a fungicide. The consumption of this material for the control of scale insects has declined, being replaced in part by oil emulsions.

Organic Insecticides.—These are compounds of carbon in combination with one or more elements, such as hydrogen, oxygen, sulphur, nitrogen, phosphorus, chlorine, and bromine. Unlike the inorganic insecticides, the organic insecticides do not possess a specific element, such as arsenic, to which toxicity may be ascribed. Insecticidal action is due to a definite arrangement of the elements within the molecule and to the molecule as a whole rather than to a specific element or combination of elements.

For convenience, organic insecticides may be

divided into three broad classes: (1) those of animal origin; (2) those of plant origin; (3) those prepared synthetically. The first class includes fish oils, which may be derived from either plant or animal life of former geological periods. Owing to their comparatively low toxicity, materials of animal origin do not appear to be promising sources of insecticides.

Tobacco, pyrethrum, derris, and *Lonchocarpus* (cube or barbasco) are the more important plant insecticides. Quassia, sabadilla, and hellebore are of lesser value. The insecticidal principle in tobacco is nicotine, which is largely used as an aqueous solution of the sulphate. When mixed with soap this solution is very effective against many sucking insects, particularly aphids. Pyrethrum flowers, a species of chrysanthemum, are grown largely in central Africa (Kenya, Belgian Congo, Tanganyika). As many as 20 million pounds of pyrethrum have been imported into the United States in a single year. Pyrethrum mixed with talc or other diluent is used against cabbage caterpillars and other agricultural insects. Its principal use, however, is in the manufacture of sprays and aerosols for combating household insects.

Derris and *Lonchocarpus* roots are imported from Indonesia and South America, respectively. These roots contain rotenone as well as other active principles. The high potency of rotenone against insects is realized from the fact that it is 15 times as toxic as nicotine to the bean aphid and 30 times as toxic as lead arsenate when fed to silkworms. More than 3 million pounds of these roots are now imported annually for the preparation of dusts and extracts. The dusts, made by mixing the pulverized roots with clay or talc, are used to combat cabbage caterpillars, the Mexican bean beetle, the pea aphid, the pea weevil, and some other insects. The powdered roots may also be suspended in water and used as sprays. The extracts are often mixed with pyrethrum extracts or certain synthetics for incorporation in household fly sprays. An American plant, the devil's-shoestring, also contains rotenone in its roots, and it may be possible to produce this valuable insecticide in the United States. Hellebore is used to a limited extent as a mild stomach poison, particularly against currant worms. The use of quassia as an insecticide is limited largely to the control of aphids on hops.

A large number of plants yield essential oils, and many of these, such as the oil of citronella, are mosquito repellents. Geraniol, a constituent of Java citronella oil, is used to lure Japanese beetles to traps. Pine tar oil, produced by the destructive distillation of longleaf pine, has been used to protect animals against the screwworm fly. Petroleum oils also are used to control insects. For application on growing plants they must be carefully refined to remove the greater portion of the unsaturated compounds. These oils, emulsified in water with soap or other emulsifying agent, have to a considerable extent replaced lime-sulphur solution for the control of scale insects on fruit trees. The lower boiling fraction, such as kerosine, is used as a vehicle for extracts of pyrethrum or derris or various synthetics to make household fly sprays.

A large number of synthetic organic compounds highly toxic to insect pests have been discovered and developed since the early 1940's. The products that have attracted greatest attention may be divided into four broad classes—

chlorinated hydrocarbons, organic phosphorus compounds, compounds that are especially useful with pyrethrum, and synthetic pyrethrinlike esters. The last mentioned compounds are almost identical in structure with the insecticidal principles in natural pyrethrum, and, like these, exert a rapid paralytic action on insects. This is especially important in controlling disease-carrying insects.

The chlorinated hydrocarbons that have attracted widest attention are DDT, TDE (DDD), methoxychlor, benzene hexachloride, chlordane, toxaphene, heptachlor, aldrin, dieldrin, and endrin. A number of organic phosphorus products have been widely explored and found to be especially useful in controlling a wide range of agricultural insect pests, including mites and such soft-bodied insects as aphids, thrips, and mealybugs. Among the phosphorus compounds that have been widely studied are parathion, malathion, demeton, tetraethyl pyrophosphate, DDVP, and Phosdrin. Piperonyl butoxide, sulfoxide, propyl isome, and MGK 264 are coined designations for products that have been especially useful in increasing the effectiveness of pyrethrum. Sesamin, a minor constituent of sesame oil, is also of value for this purpose. Such materials are known as synergists.

Many materials are used as fumigants. The oldest is sulphur dioxide, which is highly effective against bedbugs and other household insects; but is now seldom used because of its corrosive and bleaching action. Carbon disulphide has been extensively used to kill weevils in grain; but on account of the fire and explosion hazard, less dangerous materials have been put on the market. Among these are chloropicrin, ethylene dichloride, propylene dichloride, methyl bromide, and a mixture of ethylene oxide and carbon dioxide. These materials are relatively free from fire hazard and have come into large-scale use for the fumigation of all sorts of stored products. Hydrocyanic acid is employed for the fumigation of buildings and ships. A dichloropropane-dichloropropene mixture finds extensive use as a soil fumigant.

Other organic insecticidal materials include soaps, which are effective against aphids but are generally used with other more potent materials, such as nicotine, and also to emulsify oils in water. The neutral oils from coal tar have a limited use as dormant sprays, but are too injurious to plant life to be applied during the growing season. Naphthalene is used in the manufacture of moth balls and is also valuable as a soil fumigant against wireworms. Paradichlorobenzene is used to combat clothes moths and the peach borer. Coal-tar creosote is the principal wood preservative for impregnating telephone poles, fence posts, and railroad ties, and has been widely used in constructing chinch bug barriers and for proofing timbers against termites. Sticky flypapers are made from castor oil and rosin, and the latter is also used in making soaps. Rosin residue, a tacky material remaining after the distillation of rosin, is a valuable adhesive for use with derris powder. Beta-naphthol is used in corrugated-paper bands which are placed around the trunks of apple trees to trap and poison codling moth larvae; metaldehyde has shown surprising efficacy in the control of slugs, and diphenylamine is recommended for application to wounds on domestic animals to protect them against screwworms (blowfly larvae).

Angelica seed oil and a synthetic organic chemical, sec-butyl 6-methyl-3-cyclohexene-1-carboxylate are highly attractive to the Mediterranean fruit fly. Since the 1940's extensive studies have been under way to find chemicals repellent to mosquitoes, chiggers, and biting flies. Benzil and benzyl benzoate are repellent to chiggers; dimethyl phthalate to mosquitoes and mites; 2 ethyl-1, 3-hexanediol, Indalone, and dimethyl carbate to mosquitoes, chiggers, and fleas. A mixture of Indalone, dimethyl phthalate, and the ethyl hexanediol is used as an all-purpose insect repellent. N N-diethyltoluamide has been found to be an outstanding all-purpose repellent.

Useful information on insecticides, as well as on the more than 6,000 species of injurious insects against which insecticides are employed, will be found in publications of the Entomology Research Division of the United States Department of Agriculture. Various state agricultural experiment stations also issue information on this subject.

INSECTIVORA, ĭn-sĕk-tĭv'ô-râ, an order of mammals that feed chiefly on insects. It includes the shrews, moles, and hedgehogs. Insectivores exhibit many characteristics of primitive mammals, including small cerebral hemispheres in the brain, incomplete palate, and certain peculiarities of the teeth. The living species, together with fossil relatives from as long as 50 million years ago, comprise the animals most closely related to the first placental mammals. The order never has been represented by many species and even today is predominantly restricted to highly specialized environments or isolated islands, as is the case with surviving members of any primitive group.

The first insectivores, known through fossils from the Cretaceous deposits of Mongolia, resembled modern hedgehogs. Moles and shrews evolved later, but the size of the various insectivores never increased much more than in the first small hedgehogs. The largest member of the group is the tenrec, its tailless body measuring about 20 inches in length. A related form, almost as large, is the *Solenodon* of Haiti and Cuba, which looks like a rat with an elongated snout. Perhaps the greatest concentration of insectivores occurs on the island of Madagascar, presumably because the long isolation of that island from the mainland has protected the insectivores from competition with other placental mammals. The most important of the insectivores for students of evolution is undoubtedly the elephant shrew (*Macroscelides*), a small hopping ratlike animal with a greatly elongated snout. It is found in Africa and is almost unknown as a fossil, but shows many affinities to the tree shrews, which are usually considered among the primate mammals, the same order to which humans belong.

The living insectivores have paid a heavy price for survival, their ability to adapt them-

selves to any changes in environment being limited by their peculiar specializations. The moles (*Talpa*) have forelegs or both pairs of legs specialized for digging, but have lost their eyes and require a very humid atmosphere for survival. Outside their humid burrows they perish from desiccation in a very short time. The shrews escape detection by invading habitats placing a strong selective advantage upon small size, but the great increase in body surface relative to body mass leads to rapid heat loss, and no doubt partly for this reason they have to eat every few minutes, day and night. Physiologists report that shrews have higher rates of oxygen consumption in relation to body weight than any other mammals, and a brief shortage of food is sufficient to kill the animal by interfering with the maintenance of its rapid metabolic rate. The span of life of most insectivores is also comparatively brief, even under optimal conditions. See also HEDGEHOG; MOLE; SHREW.

INSECTIVOROUS PLANTS. See CAR-NIVOROUS PLANTS.

INSECTS, ĭn'sĕkts, the common English name applied to those small animals variously known as springtails, grasshoppers, locusts, cockroaches, walking sticks, termites, dragonflies, bugs, lacewings, beetles, weevils, moths, butterflies, mosquitoes, fleas, flies, ants, bees, wasps, and by many other names. To the layman they are all "bugs." It is interesting and important to note that insects constitute the world's largest group of animals from the point of sheer numbers and kinds.

For some 250 million years insects have flourished on land and in fresh water and to a much lesser degree in salt and brackish water, in Arctic wastes and tropic jungles, and in barren deserts and grassy prairies. This is because they have developed special and elastic adaptations to meet all the varied conditions and changes that have occurred on the earth during this long period of time. Yet during these aeons insects have not been greatly altered either in size or form. Their capacity for survival cannot be underestimated.

The remarkable female has been the founder, the perpetrator, and the multiplier of the species. An Australian queen termite may lay up to 360 eggs in an hour and as many as a million in her lifetime, thought to be from 6 to 15 years. In certain species of aphids in particular, the female is the only sex; males either do not exist at all or occur only occasionally. This phenomenon, known as parthenogenesis (reproduction without fertilization by the male sperm), is common among these fragile insects and not unusual among many other insects. Most of the common species of aphids reproduce in this manner throughout the spring and summer, and may continue in this way almost indefinitely. In the colder temperate regions sexual forms appear in late fall and winter. After mating, the females lay eggs on the host plants, and all living forms perish during the winter.

Another very interesting phenomenon, in which there is more than one form of the same sex, is known as polymorphism. This is well illustrated by plant lice of the genus *Periphyllus*,

all of which live and feed on maple trees. As many as 17 distinct forms occur within the ordinary life cycle of one year. The most important links in the chain of individual forms are minute, microscopic females which estivate on the leaves of the tree, producing sexual forms in the fall of the year. The latter lay the overwintering eggs, and all adult forms perish during the winter. Polymorphism really reaches its peak among termites, especially in the Australian genus *Eutermes*, which has differentiated into no less than 32 species.

Of all the methods of insect locomotion, flight is the most wonderful and important. The light, stout, muscular bodies and strong, light wings of some insects make them masters of aerial maneuvering and enable some of them to travel great distances. Certain locusts regularly migrate every year. Some make relatively short flights, whereas others may travel 100 or more miles, thus becoming international problems because they lay eggs which attain adulthood in one country and then migrate to—and devastate—another country miles away.

Most insects make dispersal flights of short distances during the spring, summer, and fall seasons. Some of these are directional, while others are occasioned by the urge to seek food or suitable hibernating or winter quarters. It is generally believed that many insects regularly winter in Mexico and migrate northward during the spring and summer, their progeny returning home again late in the summer or in the fall.

Fresh-water Insects.—Although insects are mainly creatures of the land, there are many that have adapted themselves in varying degrees to an aquatic and semiaquatic environment. In this connection it is well to point out that insects have accommodated themselves almost exclusively to fresh water, while the great expanses of salty oceans and bays are much less populated with insect life. Many insects pass only the immature stages in the water and spend their adulthood on land or in flight.

The most primitive of these insects are the springtails of the order Collembola, which live in very damp places. Certain species congregate on the surface of snow and water. The common springtail, *Xenylla maritima* Tullb., lives on seashores; whereas the marsh springtail, *Isotoma palustris* (Müller), occurs under wet leaves and mosses and appears in great numbers on the surfaces of fresh-water pools.

Of all aquatic insects, the mayflies are the most common. The females are very prolific, and the hatching of the eggs and subsequent development are rapid; the whole life cycle may be completed in six weeks. The active immature stages, called naiads, live in fresh-water streams, lakes, and ponds. The fragile, winged, short-lived adults often emerge from large bodies of water, like the Great Lakes and rivers of North America, in such enormous numbers that their dead bodies are cast ashore in great windrows. The living forms are important as food for game fish, birds, and other animals. These insects are abundant in North America east of the Rocky Mountains; they also occur in great numbers throughout the temperate and tropical areas of the world. The order is a relatively small one consisting of about 150 described genera and 1,270 species. The common *Hexagenia bilineata* not only is widely distributed in North America but is also neotropical and African. The virgin mayfly, *Polymitarcys*

virgo (Olivier) 1791, is the commonest species in Europe. The Papuan mayfly, *Plethogenesia papuana* (Eaton), which occurs in countless numbers on the Fly River, New Guinea, is believed to reproduce only in the subimago stage. The adults of all species are such attractive baits that fishermen have devised artificial imitations called drakes or drakeflies.

The so-called water scorpions are slender bugs with long respiratory filaments. They swim awkwardly on the surface of the water but are more skillful on the bottom or crawling on submerged water plants. They are predaceous on other more helpless insects. *Nepa apiculata* Uhler and *Ranatra americana* Montandon are the commonest North American species.

The giant water bugs of the family Belostomatidae are poor and erratic swimmers. These, the largest of American insects, might well be called the demons of fresh-water ponds, lakes, and brooks where they feed upon living aquatic insects, snails, tadpoles, and the young of many other aquatic animals. They deposit their eggs on floating pieces of wood, leaves, and in some species on the backs of the males. The adults fly only on warm summer evenings, and from their habit of accumulating around lights in towns and cities situated near bodies of fresh water they are frequently referred to as electric-light bugs. Common throughout North America is *Lethocerus americanus* (Leidy). The tropical *L. indicus* Stål, a large species attaining a length of four inches, occurs from China and India southward to northern Australia. The largest species appears to be the South American *L. grande* (Dimmock) which is four and one-half or more inches in length.

Another family, the back swimmers (Notonectidae), are much smaller insects, being scarcely more than one-half inch in length. They are peculiar in that they swim back downward, using their oarlike hind legs to propel themselves rapidly through the water. Closely related to them are the water boatmen, which are somewhat similar in action and appearance. Their eggs are attached to water plants. They live in either brackish or fresh water, which they often leave on warm summer nights to swarm around electric lights. The Australian genus, *Micronecta*, lives in sponges. The so-called European water cricket, *Corixa geoffroyi* Leach, is one of the largest species, attaining 15 millimeters in length; it occurs also in North Africa and central Asia. The Mexican species of the genus *Arctocorixa* is so abundant in the warm fresh waters of that country that their eggs may be dried by the ton and used as food for domestic poultry and fish.

Sialids and corydalids (order Megaloptera), also called alderflies, humpbackedflies, orlflies, dobsonflies, and fishflies, are fresh-water insects, the larvae of which are choice fish bait for country lads in the Middle and Eastern states. The larvae of the large dobsonflies are especially attractive to bass and trout.

The caddisflies of the order Trichoptera form an important diet of game fishes and are therefore beneficial. Some 3,600 species have been described. *Neuronia semifasciata* Say, the largest North American species, lives in bogs and swamps of the eastern United States. The larvae of caddisflies, called caddisworms, live within self-spun cases which are frequently decorated with bits of wood, leaves, small stones, and other debris. At rest the larvae are completely hidden within their

cases; when they are crawling about, only their heads and legs are exposed, and these may be suddenly withdrawn into the cases when danger threatens. Some species living in swift mountain streams construct bags or nets to trap their food. *Chimarra aterrima* Hagen of eastern North America builds silken nets over stones; others spin trumpet-shaped catching nets. Food caught in these devices consists chiefly of algae, diatoms, and other plant life; many species are predaceous on aquatic insects and other small animal life. Pupation occurs in the case, and the adults emerge in the water and escape into the air. The adults are winged and look somewhat like certain moths. Adults of the Australian and New Zealand snowflake caddisflies of the genus *Smicridea* are white, and in flight resemble a snowstorm.

In the genus *Amphizoa* of the order Coleoptera there are only four species of American water beetles living in fresh-water streams along the Pacific coast. The diving beetles of the family Dytiscidae constitute a very large cosmopolitan group of predaceous beetles. The larvae feed upon other small animal life of fresh water. These beetles have dull to brilliant colors and vary in size from small to large, *Dytiscus latissimus* Linn., 36 to 44 millimeters long, being the largest European species. The family consists of some 90 genera and over 2,000 species.

The small whirligig or gyrenid beetles which gyrate on the surface of still waters are widely distributed. They vary in size from the small European *Gyrinus minutus* Fab., 3.5 to 4.5 millimeters, to *Macrogyrus* of Australia, 12 to 15 millimeters in length.

The water scavenger beetles, or the Hydrophilidae, consist of 1,700 species which are mostly tropical. The largest European species is the great black water beetle, *Hydrous piceus* Linn., 35 to 50 millimeters; the largest in North America is *H. triangularis* (Say), 23 to 37 millimeters in length.

The European turnip mud beetle, *Helophorus rufipes* Bosc, is a land form feeding on roots of turnips in England.

Marine and Brackish Water Insects.—It is rather remarkable that insects, so numerous on land and in fresh water, are so poorly adapted to the brackish and salt waters of the earth. Nevertheless, in the brackish waters of land areas there are a goodly number of representatives, and along the seashores and even on floating seaweeds in mid-ocean insects do occur. Many groups of insects, especially scavengers, inhabit the beaches. Among these the maritime earwig, *Anisolabis marina* (Gene), and other related species forage along the seashores of North America and the Old World. Flies, beetles, and Collembola are among other insects inhabiting the shores. The wingless marine water striders like *Halobates micans* Esch. live on the surfaces of deep lagoons on the open oceans of Micronesia; others live on beds of seaweeds in the Sargasso Sea miles from land. *Hatovelis* occurs in small sheltered coves; the minute males ride on the backs of the females to keep from being separated. The marine midge, *Pontomyia natans*, lives in the lagoons of Samoa. The females are larviform, and the males swim with the wings. Another strictly marine insect is the Australian and New Zealand caddisfly, *Philanisus plebejus* Walker, the larvae of which inhabit rocky ocean pools along the coasts. Non-biting salt-water gnats are *Clunio murinus* Haliday, *Psammothomyia pectinata* Derby, *Thalas-*

somyia frauenfeldi Schiner of Europe, and the Japanese *Clunio pacificus* Edwards, which is only 2 millimeters long. The males are winged, and females are apterous. Another gnat, *Belgica antarctica* Jacobs, lives in the sea around Patagonia.

The brackish and salt-water mosquitoes are noted for their great numbers and pestiferousness to humans as well as to domesticated and wild animals. Certain species breed along the seashores, and others in alkali lakes and ponds where the salt content is not too great. Many anopheline mosquitoes, the world over, breed in water with a salt content as high as 3 per cent; they are not only vicious biters but often vectors of malaria, and may be classed among man's most noxious enemies. No less than 85 species and varieties of these mosquitoes are known. Other pestiferous salt-marsh mosquitoes belong to the genus *Aedes*, of which there are six very important vectors of malaria.

STRUCTURE AND MODE OF LIFE

Anatomy.—Insects are among nature's greatest anatomical achievements and are admirably equipped to hold a fair place in her economy. They are small and capable of reproducing in tremendous quantities. In versatility and numbers they excel all other animals. Their geological history indicates their very early presence in Siberian fossils and in North America.

Basic insect body plan.

The exoskeleton or outer cellular layer is an elastic, chitinous cuticle, which is regularly shed to permit developmental growth. The head capsule, made up of sclerites which are strongly cemented together, supports the antennae, the mouth parts, three ocelli (simple eyes), and the two large compound eyes, each composed of many small facets. In some insects, such as aphids, leafhoppers, coccids, cicadas, and their close relatives, the mouth parts are fused together to form a piercing and sucking rostrum, whereas in other groups they are adapted for biting and chewing. The thorax joins the head and abdomen. It is composed of three segments: the prothorax, mesothorax, and the metathorax. These are in

turn made up of sclerites, including the scutellum. The thorax has great muscular strength and supports the legs and the one or two pairs of wings; it is attached at the rear to the abdomen, which is often the largest portion of the adult body. It is composed of 10 or 11 segments, and contains the genital organs, the ovipositor or egg-laying organ, and other specialized parts. There are innumerable variations in connection with all of these organs.

Types of insect mouths.

Inside the insect's body are far more complicated organs, most of which are beyond the scope of this account. Suffice it to call attention to some remarkable ones. Of these, the auditory organs are situated on the abdomen of some, on the forelegs of locusts, and on the antennae of a great many other insects. The nervous system consists of a double ventral cord connected also by a double nerve cord with a connecting ganglia in each segment. Nerves reach all other parts of the body and its appendages. The muscular system consists of large fiber bundles of striated muscles attached to the body walls and the various appendages. The digestive system includes the fore and hind guts, gullet, crop, gizzard, and tubular stomach, which empties into the coiled intestine, and is voided through the rectum. There are also secretory organs and the paired Malpighian tubules which are chiefly urinary in function.

Circulatory System.—Insects, for the most part, have an open circulatory system; the blood fills the body cavity, bathes all tissues freely, collects beneficial and waste materials from the digestive system, glands, and other organs, and distributes the waste to the Malpighian tubules. The heart or dorsal tube is the pulsating organ;

that part of the heart passing through the thorax is known as the aorta. The blood of most insects is without hemoglobin and therefore appears whitish or yellowish in color. It is remarkable that hemoglobin does occur in the blood gills of the larvae of certain midges, gnats, caddisflies, caterpillars, and beetles.

Respiration.—Most insects breathe through a closed system of elastic branching tracheae and tracheoles, somewhat after the pattern of the closed system of mammals: the system functions like the arteries, veins, and capillaries of higher animals, only air and not blood aerates the tissues directly. Larger air sacs of varying sizes, which are formed by dilations of the tracheae, occur in grasshoppers, flies, and bees. The entire abdomen of the cicadas constitutes an air reservoir. The openings or spiracles or stigmata of this system occur along the sides of the body and usually consist of 10 pairs—two pairs on the thorax and eight on the abdomen. Most aquatic insects breathe by means of tracheal gills, but certain ones carry an air supply with them under water.

Nervous System.—The principal organs of the nervous system are located ventrally along the median line and consist of a series of ganglia or nerve centers connected by a double nerve cord and radiating nerves and nerve fibers to all parts of the body. The brain or supraoesophageal ganglion is located in the head above the oesophagus and innervates the antennae, eyes, and labrum. The mushroom bodies, developed in ants and bees, are groups of cells whose fibers unite to form stalked nerve structures in the protocerebrum, or the larger part of the brain which controls the eyes and ocelli. The suboesophageal ganglion, situated below the oesophagus, innervates the mouth parts except the labrum. Two cords, the *crura cerebri*, one on each side of the oesophagus, connect the brain and the suboesophageal ganglion. The thoracic ganglia may consist of three separate nerve centers located in the different segments or they may be fused into one or two ganglia in some insects. The abdominal ganglia are normally distributed, one in each segment, or they may be fused into fewer centers. Wherever a ganglion is located in a segment, it becomes the nerve center of that particular part of the body.

Sense Organs.—Sight is present in nearly all insects excepting a few subterranean and cave-dwelling forms. Certain immature forms have only a pair of simple eyes, whereas the great majority of adult insects have two large compound eyes—made up of a large number of facets—and three simple eyes or ocelli, which are arranged in a triangle on the vertex and frons of the head. Organs of taste and smell are highly developed in all forms, and many insects rely upon these senses to find their food.

Metamorphosis.—One of the really remarkable phenomena of the animal world is the metamorphosis or growth and development of insects from egg to adult. Metamorphosis may be of the *primitive, simple, or complex* type.

Primitive metamorphosis is an apterous condition in which there are no distinct changes evident, except in size and sometimes in coloration. Examples: the minute proturans, silver fish moths or slickers, and the snowfleas.

Simple metamorphosis is a type in which certain organs, such as gills of aquatic larvae or naiads, are evident. Examples: most of the aquatic insects, grasshoppers, dragonflies, mayflies.

Complex metamorphosis is a type in which the larval stage is altogether different in appearance from the adult. Included are the scorpionflies, raphidids, lacewings, flies, fleas, beetles and weevils, butterflies and moths, ants, bees, wasps, sawflies, horntails, gallflies, and the very large group of parasitic wasps.

Eggs.—The eggs are not greatly different from those of other invertebrate animals. All are furnished with a polar micropyle, consisting of one or more microscopic openings through which the male sperm enters and fertilization is accomplished. Eggs of many insects also have an operculum, a lid or cap by means of which the young emerge. The eggs are necessarily small, varying from 0.1 to 6 millimeters or perhaps a little larger. They may be beautifully colored and marvelously sculptured, and are deposited singly or in clusters; a single female may lay from a few to a thousand. Termites, ants, and bees appear to be the most prolific. The eggs may be laid in a cement matrix, in a capsule, or may be

object preparatory to development into the pupal or chrysalis stage. A great variety of other methods are employed in which to pass the resting and reorganization condition: in wax cells, silken and hair cocoons, cases, and nests in wood and

Primitive metamorphosis of the silverfish.

covered with an exudate together with scales from the female body. Water insects may also deposit them in gelatinous masses or in strings.

Larva.—This term is usually applied to the first stage of those higher insects that have complete metamorphosis. They are quite different from the adults and in many cases bear no resemblances to them whatsoever. Some of them are better known under such names as ant lions, bagworms, cankerworms, caseworms, caterpillars, flat-headed borers, grubs, leaf rollers, leather-jackets, loopers, maggots, silkworms, slugs, skipper, spanworms, tomato worms, warbles, white grubs, waxworms, wireworms, wrigglers, and others. There are many types of these larvae which are frequently referred to as worms, but it is not possible to describe them by their technical designations. Among the plant-eating forms this stage is the most destructive to vegetation, whereas with respect to health the adults are the "biters" and carriers of animal diseases.

When full grown, the larvae of most butterflies and many other insects usually fasten themselves at the posterior end to a twig or other

Simple metamorphosis of the chinch bug.

soil. The resting and reorganization period is a vulnerable one for insects; ordinarily they are defenseless at this time, and so they have been enabled by nature to camouflage themselves and to seek protective burrows and other concealment. That these devices have been successful is indicated by the fact that insects are the most numerous and varied of all the higher types of animal life.

Protective Devices.—Insects are often referred to as hexapods because in the adult condi-

Complex metamorphosis of the Monarch butterfly.

tion they possess three pairs of legs. This allows for the loss of one or more legs, all of which may be regenerated to some extent. Wings, antennae, and cerci are also deciduous appendages. The insect body, or exoskeleton, is hard, tough, light, and elastic, capable of renewal, and resistant to

corrosive chemicals. It is further protected by hairs, scales, spines, rugosities, and the wings, which are folded like a roof when the insect is not in flight. Insects have also developed protective and warning colorations, and use other devices of mimicry. They may be shielded somewhat by bizarre color patterns, by their grotesque forms, and by noises they can make—loud stridulations, such as buzzing and drumming. Safety may also be assured by alertness and keen ability to perceive motion. Among other protective devices are biting, jumping, snapping, death-feigning, flight, and secretive nocturnal and seasonal habits. For use against their enemies insects have a variety of weapons, such as excretions of protective waxes, resins, and offensive and poisonous glandular fluids and gases. Sticky and volatile fluids are employed for carrying on offensive warfare. Stings are effectively used by bees and wasps. Protection during the various stages of insect development (eggs, larvae, pupae, and adult) is provided by specially constructed living quarters, as in the cases of caddisfly larvae, certain caterpillars, the paper nests made by wasps in which to rear their young, as well as webs, cocoons, spittle, and galls.

Mimicry.—One of the most remarkable phenomena among insects is mimicry—the resemblance of one insect to quite different, unrelated species. Some classical examples are the close similarity of the viceroy butterfly to the monarch butterfly, the drone fly to the honeybee, certain robber flies to bumblebees. The small beetle, *Casnonia*, is very like the ants in whose nests it associates. Other examples are to be found in a great many widely separated groups of insects.

Luminosity.—Many insects are able to generate light. Marvelous are the fireflies of the family Lampyridae, which are beetles, and a few other insects belonging to the families Lycidae, Phengodidae, Drilidae, Cantharidae, and the springtails of the genera *Anurida*, *Achorutes*, and *Onychiurus*. The North Carolina fungus gnat, *Platyrura fultoni*, lives in wet dark places and glows at both ends. The adults of the European midge, *Chironomus plumosus*, are luminous. Most remarkable is the New Zealand glowworm, the larva of the mycetophilid fungus gnat, *Arachnocampa luminosa* Skuse, which lives in the famous Waitomo Caves, New Zealand. The small, slender larvae spin webs upon which they live in wet crevices and on the surfaces of the moist rock walls. They move with agility when disturbed. The colonies are sufficient to cover large surfaces, and when there is complete stillness the whole cave begins to glow with a mystic golden light like that of a starry sky. The light is steady rather than flashing. Other colonies of great size occur in New South Wales, Australia.

Diseases of Insects.—Like all other animals insects are subject to diseases which play a large part in keeping them in check. The most important are those caused by bacteria and fungi. These important checks aid man in his struggle with these small relentless competitors.

Social Insects.—There is instinctive cooperation among the so-called social insects, such as the ants, bees, and wasps, which, in all cases, is based upon a caste system. This system is the result of a hereditary condition in which there are nonsexual or aborted individuals incapable of reproduction. The sterile or aborted insects are bound to servitude and do all or most of the work and provide the food for the colony.

Termites are a most highly specialized group of social insects. They stem from the prehistoric age and are among the oldest living inhabitants of the earth. They are remarkable because of their highly organized system of castes, which is patterned somewhat after that of the ants. They have rather soft bodies; those individuals that are confined to the darkness of their nests are pale, whereas the migrating and winged aerial forms are usually brown and black. Termites vary in size from very small workers, which are only a few millimeters, to others an inch or more in length. They are rarely encountered except during their mating flights when they may swarm in great numbers from the ground or from dead wood, frequently after the first rains in the temperate regions. They get the name "white ants" from their general resemblance to the common ants, which are quite distantly related to them. Their very complicated caste system, not fully understood even by experts, consists of *reproductives*, winged and wingless, and *aborted forms*, workers and soldiers. The reproductives, the sexual males and females, are the life of the colony, responsible for maintaining it and founding new colonies.

A colony consists of a royal pair, king and queen, which are the parents. The males are extremely small, whereas the queens may be as large as a man's thumb. After mating, the queen begins to lay eggs, producing thousands of them annually over a period of from 5 to 15 or more years. Other individuals of the colony are the winged and wingless termites, the apterous workers, as well as the large-headed soldiers which defend the nest against the attacks of other insects. Soldiers of the genus *Nasutitermes* have heads prolonged into a snout employed to smear a sticky secretion upon their enemies.

Termite nests are either subterranean or aerial, and the great termite mounds are among the most remarkable objects of nature. They occur mostly in the warmer tropical and subtropical regions of Australia and Africa. None of them seem to occur in the Western Hemisphere, although common termites are abundant in that half of the world. In the temperate regions of North America, termites are chiefly subterranean in habit.

Termites are without doubt the most prolific of all insects. An investigation of their reproductive capacity was made by the Councils of Science and Industrial Research of Australia in 1938. Selecting a small mound one and one-half feet high and four feet wide at the base, the council assembled the following facts about the Australian termite, *Eutermes triodiae* (*Nasutitermes exitiosus*):

Total population	1,800,000
Workers	1,560,000
Soldiers	200,000
Young	40,000
Humidity	above 95 per cent
Temperature	relatively high

Termites feed upon dead and dying vegetation, which is converted into foods available for plants; they thus have a real place in the general economy of nature. They are troublesome and destructive to man because they destroy wooden buildings, fences, bridges, and all other plant products.

INSECTS AND MAN

Insect Biters.—In addition to mosquitoes, which are among the greatest tormentors of the human race and its domestic animals, many other

INSECTS

(1) *Spiloniia fusca*, a wasp-like hover fly. (2) *Musca domestica*, the common housefly. (3) *Dolichovespula maculata*, the white-faced hornet. (4) *Cynomya mortuorum*, a bluebottle fly. (5) *Urocerus flavicornis*, a horntail. (6) *Eulonchus smaragdinus*, a small-headed fly. (7) *Ceratogaster fasciata*, an ichneumon fly. (8) *Cuterebra buccata*, a large botfly. (9) *Doros aequalis*, a wasp-like hover fly. (10) *Lampria Mexicana*, a robber fly. (11) *Dasymutilla klugii*, a velvet ant. (12) *Bombus huntii*, a bumblebee.

Oil beetle

insects add to man's misery. Buffalo gnats, black flies, and turkey gnats belonging to the family Simuliidae are among the most annoying and persistent. The larvae live in fresh-water streams, and the adults continually harass fishermen, vacationers, and domestic animals. An African species transmits a filarial disease to man. The most notorious American species are the Adirondack black fly and the white-stocked black fly in the eastern United States, the turkey gnat in the Rocky Mountain region, and many others. Biting midges, punkies, no-see-ums, and sand flies belong to another family of tormentors of all higher animals, especially man, throughout the world. They are often so small as to be scarcely discernible, but their bites are sharp and usually very painful. The larvae live in fresh and brackish water. Some tropical species transmit filariasis to man. Sucking lice of the order Anoplura and fleas belonging to the order Siphonaptera, both of which in years past were the most intimate and annoying pests of the human race, have almost entirely disappeared as a result of sanitation and the discovery and intelligent use of new and very effective insecticides.

Insects and Human Diseases (Medical Entomology).—A considerable number of insects are carriers and vectors of human diseases. In ancient times, before man had knowledge of either the diseases or the vectors, he became the victim of many terrible scourges that took millions of lives. Of these early maladies, black death or bubonic plague was the most destructive. The great plague of 1665 in London killed about 70,000 out of a population of about 450,000. The microscopic germ *Pasteurella*, causing this terrible disease, developed in fleas which carried the plague to humans. Rats, too, contributed to the transmission of the disease as the host carriers of the fleas. It is comforting to know that the effective destruction of rats and fleas has practically eliminated this scourge from civilization.

Other important insects bearing diseases that are associated with man are the tsetse flies belonging to the genus *Glossina*, of which there are some 21 species and a considerable number of varieties. All occur in tropical, subtropical, and equatorial Africa, excepting only a single species reported in Arabia. Of these flies, the *Glossina fusca* (Walker 1849), consisting of 10 species and several varieties, plays a minor role in the transmission of African sleeping sickness, a disease of high mortality caused by *Trypanosoma gambiense* Dutton. Another more important group, the *Glossina palpalis* (Robineau-Desvoidy 1830), which contains seven species and a number of varieties, transmits Gambian sleeping sickness produced by *T. gambiense* to man and by *T. uni-forme* Bruce to sheep and goats; souma, a disease of cattle and horses, is caused by *T. vivax* Ziemann. The *Glossina morsitans* Westwood 1850 group, with six species and two varieties, is the most important and serious vector of the trypanosomes causing Rhodesian sleeping sickness; *T. brucei* Plimmer and Bradford causes nagana of cattle, and *T. suis* Ochmann of swine.

Perhaps the commonest of mankind's most wretched diseases is malaria. It is worldwide in distribution and has caused much misery, but it is rapidly being exterminated throughout most of the world. The disease appears to be as old as the human race, but it was not until 1897 that the Englishman, Sir Ronald Ross, in India, discovered that mosquitoes were the carriers and vectors of

malaria. Later the Italian zoologist, Giovanni Battista Grassi, found that only mosquitoes of the genus *Anopheles* were capable of transmitting the disease. Treatments for malaria with cinchona bark, the source of quinine, were known in Peru by 1638 or earlier, when the bark may have been used to cure the condesa de Chinchón of the fever. The bark was introduced into Europe in 1640 and subsequently given the scientific name *Cinchona officinalis* by Linnaeus. A great amount of exploratory work and research has been done and continues to the present time in order to secure and produce the best possible species and hybrids of cinchona for making the finest types of medicinal quinine.

Yellow fever, another very serious tropical disease, was also a terrible scourge to the human race until the discovery that it and dengue fever were transmitted by the mosquito *Aedes aegyptii* (Linn.). Insects are responsible also for the transmission of many other serious diseases of man and his domesticated animals.

Insects as Food for Man.—Although insects are among the commonest and most abundant forms of animal life associated with the human race, they are the least known and the most grossly misunderstood by civilized peoples. Aboriginal races, however, appreciated the many values of insects and ate a great many of them as well as insect products, such as honey and honeydew. Ingrained in most of us is the fallacious belief that insects, such as aphids, caterpillars, and fragments of all other kinds are filth. As a matter of fact, these animals—minute, delicate, soft-bodied—have throughout the ages been commonly eaten by human beings and other animals along with vegetables and fruits without ill effects and in most cases no doubt to the advantage of the consumer.

Aphids and other small species, which are common on nearly all vegetable crops, caused great concern and much financial loss to growers and canners of vegetables and fruits because of the virtual impossibility of producing these crops without their being infested by many small and obscure insects; crops are thus subject to rejection or confiscation after canning and other processing, because of insect contamination. Even though repeated applications of insecticides are made and the harvested crop is thoroughly washed and otherwise treated to eliminate the insects, it is practically impossible to remove all invisible parts from the canned or dried product. It would seem to be far safer to eat a few harmless insects than to eat fresh and canned vegetables which have been even slightly contaminated with poisons used to eliminate the insects. Many species of insects have been consumed by all races, past and present. Examination of historical documents, including the Bible and numerous authorities on ancestral man, reveals the important dietary use of insects. Anthropologists tell us that three fourths of the food of certain West coast American Indians was vegetable and one fourth animal, the latter consisting chiefly of insects.

The most generally available and preferred insects the world over were locusts, or migratory grasshoppers. They often appeared unexpectedly from unknown lands in countless numbers, and, although in most cases they destroyed the farmers' crops, they in turn became food for hungry human beings. Locusts were a regular article of diet of savage and civilized peoples in Asia, Africa, North and South America, Australia, and certain

of the Pacific Islands. Because grasshoppers are quite large and easily captured, they are readily available with little effort. Grasshoppers, bees, ants, and other insects, as well as certain insect eggs, have been purchased in food stores of many United States and Canadian cities.

In China and other parts of Asia the vast populations living on the banks and in houseboats along the lower reaches of the great rivers are favored during certain parts of the year with an inexhaustible supply of the large predaceous water beetles. They are consumed fresh, cooked, dried, pulverized in soups, and in other ways. Species eaten at the present time by the Asiatics include *Hydrous pallidipalpis* MacLeay of south China and the Indochina peninsula; *Cybister bengalensis* Aube; *C. guerini* Aube; *C. japonicus* Sharp; *C. limbatus* Fabricius; *C. sugillatus* Erichson; and *C. tripunctatus* Olivier (Hoffman 1947). In China no less than 50 species of insects are not only consumed in the daily diet but make up a considerable part of the total food intake. Some species are also considered to have unquestionable medicinal value.

The water bug, known as the giant fish killer, *Lethocerus indicus* Stål, a preferred dietary item of tropical China, India, and Australia, attains a length of four inches. A similar water bug of South America, *L. grande* (Dimmock), is even larger, measuring up to four and one half inches; in North America *L. americanus* (Leidy), the most common species, was and is still eaten by man.

In Mexico the water bugs occur in tremendous quantities in Lake Texcoco and Lake Chalco near Mexico City, especially the Aztec water boatman (*Krizousacorxia axteca* Jaczewski), the Mexican water boatman (*K. femorata* Guérin), and the commercial boatman (*Corisella mercenaria* Say), together with the Texcoco back swimmer, *Notonecta unifasciata* Guérin (Ancona, 1933), and their eggs and young. They have been used for human food from ancient times and are still so used in Mexico. They are also exported by the ton to other parts of the world, where they are sold for fish, turtle, and bird food. The eggs of the water bugs are made into a sort of caviar, and the water bugs themselves are sold in some places for chicken feed. In Mexico City one of the delicacies often praised by visiting tourists is *los gusanitos de maguey*. These are large white caterpillars that mine the fleshy leaves of various species of *Agave*. They are often offered for sale along with pulque. These caterpillars, or maguey worms, are usually fried; they are also canned and sold in grocery stores. The adult is a skipper butterfly scientifically known as *Acentrocne me hesperiaris* Kirby (*Aegiale kollari* Felder, *Teria agavis* Blasques).

In California, the Indians of the Mono Lake region gathered and ate the pupae of the ephydrid fly, *Ephydra hians* Say, which were washed up in windrows on the shores of Mono Lake by windstorms.

The large fat grubs and also the pupae and adults of many beetles have been consumed fresh, dried, or parched. The most striking examples are the palm rhinoceros beetle, *Oryctes rhinoceros* (Linn.), of tropical Asia; the American sugarcane beetle, or grou-grou, *Rhynchophorus palmorum* (Linn.), and the Hercules beetle, *Dynastes hercules* (Linn.), of the tropical Americas; and the atlas beetle, *Chalcosoma atlas* (Linn.), of tropical Africa.

Of the caterpillars of butterflies and moths, many kinds were eaten either fresh, toasted, dried, boiled, or roasted. Hairy tent caterpillars of North America, especially California, which were abundant in the spring, were singed to remove the hairs and roasted before the fire by Indians. The large larvae and pupae of the pine pandora moth, *Coloradia pandora* Blake, were dried and consumed alone or mixed with corn meal by the aborigines of western North America.

Termites have been an important food wherever they occur in tropical and temperate regions. All castes and states of them were eaten, mostly alive. The large queens of the mound-building species in tropical Africa, Australia, and elsewhere were considered a very great delicacy.

Various species of lice infesting the bodies of humans were eaten by all aboriginal races. They were devoured not only because they had a pleasant nutty flavor but also as a ritual among certain tribes.

Many insects furnished honeydew, the much appreciated manna of the Israelites, and also honey, the most important sweet available up to about 1420, when cane sugar became a commercial product. The honeybee was cultivated by the ancient Egyptians and Chinese, and with the beginning of recorded history, this remarkable insect appears in the literature of all the important civilizations of the world. Many strains have been developed in different countries in the African-Eurasian continental areas.

Insect Control.—The control of food-destroying and disease-bearing insects is necessary to protect the health, food supply, and other necessities of the human race. As populations increase, crop protection becomes more important. Scientists of all professions have joined the entomologists in the gigantic task of supplying the information necessary to guarantee adequate protection. The first effective insecticides were not developed until the mid-19th century, and since that time great progress has been made in the discovery and development of new and remarkably effective insecticides. The greatest concern in the use of insecticides is to overcome the remarkable faculty that insects have of readily developing resistance to practically all of the most effective and powerful chemicals thus far used.

The so-called biological control method appears to be a very important aid in the solution of this problem. This method employs the selection and use of certain insects that naturally parasitize and devour other injurious insects. It was first demonstrated in the control of the cottony cushion scale, which became a very serious pest on citrus trees in California, by the introduction of the vedalia, a ladybird beetle that was naturally predaceous on the cottony cushion scale in Australia. This paved the way for more experiments along this line and to the development of the modern science of biological control.

Insects of Commercial Value to Man.—

The domestic honeybee or hive bee is certainly one of man's oldest and most valuable domesticated animals. Its association with man goes back beyond dated history. It is also the most socialized insect. The adult members of the hive are divided into three castes: the fertile queen, the mother of the colony; workers, or aborted or infertile females; and the drones or fertile males. A hive or colony usually consists of from 20,000 to 50,000 individuals. The most important domestic races are the Italian, which are the most industrious;

the Caucasian and the Carniolan, which are the gentlest; and the German, which are the most hostile, but which respond to smoking. The benefits derived from honeybees are very important, the greatest being the cross-pollination of food plants and other cultivated and wild plants and the production of honey and beeswax.

During past centuries, silkworms provided the human race with the most luxurious clothing. The Chinese silkworm, whose history is obscure, has become so completely domesticated that it can no longer live without the care of man. Its important economic status is now being jeopardized by the manufacture of synthetic cloth, which may eventually result in the extermination of this valuable insect.

The cochineal dyes were derived from the dried bodies of a cactus-infesting scale insect of Mexico. The dyes, treated with mordants, produced brilliant red hues. The discovery and perfection of aniline dyes during the latter half of the 19th century did away with the use of cochineal.

The greatest early sources of waxes were the honeybees and wild bees. Wax is used by the bees chiefly for making comb in which to store the honey necessary to carry them over during the long periods when flowers and other sources are not available. Beeswax was used in enormous quantities during the Middle Ages.

The manna of the Israelites is believed to have been produced by a coccid or scale insect, *Gossyparia mannifera* (Hardwick), which feeds on the desert *Tamarix* of Iraq and Asia Minor. The sweet excretions, now called honey, accumulated under the plants. Because of lack of rain these accumulations stratified and solidified. The sugar was recovered by a process of evaporation, involving the soaking of these deposits in water. Honey is still so collected by Arabs and others.

INSIDE OF THE CUP, The, a novel by Winston Churchill, the American novelist, published in 1913. This strong polemic on the purpose and value of religion in the modern world takes its theme from the words of Jesus: "Woe unto you, scribes and Pharisees, hypocrites! for ye make clean the outside of the cup and of the platter, but within they are full of extortion and excess . . . cleanse first that which is within the cup and platter. . . ." (Matthew 23: 25-26).

John Hodder, a young clergyman from New England, called as rector to St. John's, a fashionable church in a large Midwestern city, grows increasingly dissatisfied over the work his church is doing—and failing to do—in meeting the

spiritual needs of the community. After a prolonged and painful struggle with his conscience, during which he is forcibly confronted with the evils of irresponsible wealth and financial power, he arrives at what he believes to be a more democratic, less dogmatic, Christianity—a church not for the privileged only but for all who seek to better their lives. He expounds his new views in a sermon branded as heretical, radical, and dangerous by most of his influential parishioners—among them Eldon Parr, a banker and stock manipulator, the embodiment of all Hodder was inveighing against.

The rector refuses to resign, and the issue is joined between them. Parr cannot prevent his daughter from marrying the minister; but, remaining unregenerate to the end, he can, and does, disinherit her and withdraws his support from St. John's. Meantime, many who felt they had lost all faith find their way back to a church which has been brought closer to their needs and aspirations.

INSIGNIA OF RANK, Armed Forces, in-sig-ni-à. Just as distinctive uniforms set apart the military man from the civilian, and distinguish the members of the armed forces of one nation from those of others, so insignia of rank denominate the various grades within the military, naval, and air forces of each nation. Officers, warrant officers, and noncommissioned officers, charged with varying degrees of authority, wear distinctive insignia for each grade, so that they may be readily identified by subordinates as well as by superiors.

Properly, the word *insignia* is the plural of *insigne*, but in common military usage *insignia* is employed as both singular and plural.

Insignia of military rank is a recent development in the long history of warfare. Prior to and during the Middle Ages military commanders came from the aristocracy and were easily identified by their heraldic trappings. But by the 16th century the professional army, either national or mercenary, was replacing the feudal levies, and the leaders were not necessarily nobles of the realm. During the 17th century the household troops of Louis XIV of France were given distinctive uniforms, as was the New Model Army in England. Officers wore a much more elaborate uniform than their men, but it was not until late in the 18th century that actual insignia of rank came into general use.

In the United States, the first rank insignia was devised by Gen. George Washington in 1775; generals, field officers, captains, and subalterns were to wear different colored ribbons and cockades. In 1780 a system of epaulets on one or both shoulders was adopted and with it the first of the modern insignia—silver stars for general officers. The colonel's spread eagle was adopted in 1832, and within the next decade most of the rest of the present officers' insignia appeared; that of 2d lieutenant, however, remained a blank shoulder strap until the gold bar was adopted during World War I. Chevrons of noncommissioned officers, at one time worn point down (as today by the navy and air force), have undergone many changes to keep pace with the increasing specialization of the modern armed forces.

The insignia of rank and related insignia worn by the armed forces of various nations are described below.

ARGENTINA

Army.—Officers' insignia of rank is worn on shoulder straps of service and field uniforms; that of other ranks is worn on the upper sleeve. The cap device consists of the national coat of arms in a wreath, above which is a blue and white rosette.

General of Army, General of Division, and General of Brigade: On red-edged shoulder strap, crossed gold wheat sprigs below three (two, one) 12-rayed suns in gold on red disks.

Colonel, Lieutenant Colonel, and Major: On strap edged in light green, three (two, one) gold suns on disks of branch color.

Captain and First Lieutenant: Three (two) silver disks with projecting knobs.

Lieutenant: One gold and one silver disk.

Sublieutenant: One silver disk.

Senior Warrant Officer: Two thin vertical gold interwoven stripes.

Warrant Officer: One thin vertical gold stripe.

Sergeant Major and First Sergeant: Two (one) narrow above one broad horizontal gold stripe.

Sergeant: One narrow above two broad gold chevrons, point down.

First Corporal and Corporal: Two (one) narrow above one broad gold chevron.

Navy.—Officers' rank is indicated by gold stripes around the lower sleeve of blue uniforms and on shoulder boards of other uniforms, the upper stripe forming a loop. Officers of technical corps wear colored cloth between stripes. Warrant and petty officers wear insignia on the upper sleeve.

Admiral, Vice Admiral, and Rear Admiral: Three (two, one) medium above one broad stripe.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant: Two medium stripes.

Lieutenant (junior grade): One medium above one narrow stripe.

Ensign: One medium stripe.

Chief Warrant Officer: One narrow above two broad horizontal gold bars.

Warrant Officer; Petty Officer, 1st and 2d class: Three (two, one) narrow above one broad bar.

Seaman, 1st, 2d, and 3d class: Three (two, one) narrow above one broad gold chevron, point down.

Air Force.—Officers' rank is indicated by sleeve stripes and shoulder boards, as for the navy, with the upper stripe forming a lozenge and gold wings below the stripes. Titles and rank insignia of enlisted personnel are substantially the same as for the army.

Brigadier General, Brigadier Major, and Brigadier: From the top: one medium, three (two, one) narrow, and one very broad stripe.

Commodore, Vice Commodore, and Commandant: As above, with lower stripes half as broad.

Captain, First Lieutenant, and Lieutenant: Three (two, one) narrow below one medium stripe.

Ensign: One medium stripe.

BELGIUM

Army.—Officers' rank insignia is worn on

lapel tabs, the tab color indicating branch. General officers also wear rank insignia on shoulder straps; other officers wear regimental or corps devices on shoulder straps. General officers wear on caps, and on lapel tabs above rank insignia, a stylized grenade and lightning bolts; other officers wear on caps the royal crown or regimental device. Above the cap device all officers wear a yellow, black, and red rosette. Enlisted personnel wear rank insignia on the lower sleeve.

Lieutenant General, Major General, and Brigadier

General: Three (two, one) gold stars above two broad horizontal gold bars. On shoulder straps, three (two, one) gold stars.

Colonel, Lieutenant Colonel, and Major: Three (two, one) gold stars above a broad gold bar.

Captain Commandant: Three gold stars below a narrow gold bar.

Captain, Lieutenant, and Sublieutenant: Three (two, one) gold stars.

Senior Warrant Officer: One silver star below a narrow silver bar.

Warrant Officer: One silver star.

First Sergeant Major, First Sergeant, and Sergeant: Five (four, three) diagonal stripes, spaced between second and third from bottom.

Corporal and Private, 1st class: Two (one) diagonal stripes.

Navy.—Rank of officers and chief petty officers is indicated by gold stripes around the lower sleeve; of other personnel, by diagonal gold stripes on lower sleeve. Commissioned officers have a loop in upper sleeve stripe, and wear on the shoulders narrow curved gold bars parallel to the sleeve seam. The officers' cap device is the red, yellow, and black rosette within a double oak-leaf wreath, surmounted by a crown, in gold; the device for petty officers has a single wreath. Flag officers wear two rows of gold braid on cap visor; senior officers wear one row.

Commodore: One broad (two-inch) stripe, with a gold star above the loop.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant, 1st class: Two medium stripes, with a gold star inside the loop.

Lieutenant: Two medium stripes.

Lieutenant (junior grade): One medium above one narrow stripe.

Ensign: One medium stripe.

Chief Petty Officer, 1st class: Above a medium stripe, without loop, a gold crown in wreath.

Chief Petty Officer: Above a narrow stripe, a gold crown.

Petty Officer, 1st, 2d, and 3d class: Three (two, one) diagonal gold stripes.

Seaman, 1st class: One diagonal red stripe.

Air Force.—Rank of officers and warrant officer is indicated by blue stripes edged in black around the lower sleeve of the service coat and on shoulder straps of other uniforms. General officers wear the army grenade device on lapel tabs. Titles and insignia of rank of enlisted personnel are identical with those of the army. The officers' cap device is the royal coat of arms in a pair of wings encircled by a wreath, surmounted by a crown, in gold; for

other ranks, the same above a half wreath.

Lieutenant General and *Major General*: Three (two) narrow above two medium stripes.
Colonel, Lieutenant Colonel, and Major: Three (two, one) narrow above one medium stripe.
Captain Commandant: Three narrow stripes, the upper having a loop.
Captain, Lieutenant, and Sublieutenant: Three (two, one) narrow stripes.
Senior Warrant Officer: Two narrow above one broad stripe.
Warrant Officer: One broad stripe.

BRAZIL

Army.—Rank insignia of officers and warrant officers is worn on shoulder straps and on the field cap, that of enlisted personnel on the upper sleeve. The cap device consists of the five stars of the Southern Cross on blue within concentric ovals of silver, white, green, and yellow; for officers, the device is mounted in a gold wreath; for other ranks, in stylized rays.

Marshal, General of Army, General of Division, and General of Brigade: On gold strap below Southern Cross device pierced by a silver sword, five (four, three, two) silver stars.
Colonel: On plain strap, three disks, each consisting of a silver star mounting the Southern Cross superimposed on orange and gold rays.
Lieutenant Colonel: One star above two disks.
Major: Two stars above one disk.
Captain, First Lieutenant, and Second Lieutenant: Three (two, one) stars.
Warrant Officer: Hollow silver-gray diamond.
Sergeant, 1st and 2nd class: Six (five) chevrons, point up, in silver-gray except fourth from top, white.
Sergeant, 3d class and Corporal: Three (two) silver-gray chevrons.

Navy.—Officers' rank is indicated by gold stripes around the lower sleeve of blue uniforms and, for officers below captain, on shoulder boards of other uniforms. Sleeve stripes are the same as for the Argentine Navy, including loop in upper stripe. Shoulder board insignia for flag officers and captains is as follows:

Admiral: On gold shoulder board, a silver anchor above three silver stars in triangle, the upper star having on it the Southern Cross within laurel branches.
Vice Admiral and Rear Admiral: Silver anchor above three (two) plain silver stars.
Captain: On plain shoulder board, a silver anchor above four medium gold stripes.

Air Force.—Officers' rank insignia is worn on shoulder straps of service and field uniforms and on the lower sleeve of dress and full dress uniforms; that of enlisted personnel, on the upper sleeve. The cap device is a vertical sword on a pair of wings, mounted on stylized spread wings for officers and on stylized rays for warrant officers and enlisted personnel.

Air Marshal: On gold-braid shoulder strap, below a sword and wings device, one small and four larger stars of the Southern Cross.
Lieutenant Brigadier, Major Brigadier, and Air Brigadier: Four (three, two) stars.
Colonel: On plain strap below sword and wings,

two groups of three horizontal bars each, each group having a star centered.
Lieutenant Colonel: A group of two above a group of three bars.
Major: Two groups of two bars each.
Captain, First Lieutenant, and Second Lieutenant: A group of three (two, one) bars.
Warrant Officer: Centered on a horizontal bar, the Southern Cross within a diamond.
Sergeant, 1st, 2d, and 3d class; Corporal; and Private, 1st class: Five (four, three, two, one) chevrons, point down, in gull-wing form.

CANADA

Insignia of rank of personnel of all services is the same as for the armed forces of the United Kingdom (see section in this article). In the army, the word "Canada" in metal is worn on the outer edge of the service coat shoulder strap, and is embroidered on a tab just below the battle dress shoulder seam. In the navy a similar tab is worn on all uniforms, and on seamen's cap ribbons the letters "HMCS" precede the ship's name. In the air force the word "Canada" is embroidered on a black tab just below the shoulder seam for officers; the tab for other ranks bears the word "Canada" above a soaring eagle. The wings of flying personnel bear the letters "RCAF."

NATIONALIST CHINA

Army.—Officers' and warrant officers' rank insignia is worn on shoulder straps, branch insignia on the collar. Piping on lower sleeves is in red for general officers, yellow for field officers, and blue for company officers. Rank insignia of enlisted personnel is generally the same as for the United States Army.

Generalissimo: Five gold stars in a circle.
General of the Army, General, Lieutenant General, and Major General: Four (three, two, one) gold stars.
Colonel, Lieutenant Colonel, and Major: Three (two, one) gold plum flowers.
Captain, First Lieutenant, and Second Lieutenant: Three (two, one) silver bars.
Warrant Officer: One silver square.

Navy.—Officers' rank is indicated by gold stripes around the lower sleeve of blue uniforms and by shoulder board devices on other uniforms. Line and engineering officers wear a gold circle of wheat above sleeve stripes; officers of other corps wear, between stripes, cloth backing in corps color.

Admiral of the Fleet, Admiral, Vice Admiral, and Rear Admiral: Four (three, two, one) medium above one broad stripe. On gold shoulder board, below sun on blue disk and crossed anchors, four (three, two, one) silver stars.
Commodore: One broad stripe. On gold shoulder board, silver sun and crossed anchors only.
Captain and Commander: Four (three) medium stripes. On shoulder board with two wide gold stripes, silver sun above single silver anchor above three (two) silver stars.
Lieutenant Commander: One narrow above two medium stripes. One silver star.
Lieutenant: Two medium stripes. On shoulder board with three narrow gold stripes, silver sun on blue disk above three silver stars.

Gunnery Sergeant

Staff Sergeant

Sergeant

Corporal

Lance Corporal

Private, 1st class

Lieutenant (junior grade): One narrow above one medium stripe. Two silver stars.

Sublieutenant: One medium stripe. One star.

Air Force.—Officers' rank is indicated by gold bars below a gold eagle on lower sleeve. Rated officers wear a winged three-bladed propeller on each side of collar; nonrated officers wear a winged two-bladed propeller and wheel.

General, Lieutenant General, and Major General:

Three (two, one) narrow above two wide bars.

Colonel, Lieutenant Colonel, and Major: Three

(two, one) narrow bars above one wide bar.

Captain, First Lieutenant, and Second Lieutenant: Three (two, one) narrow bars.

DENMARK

Army.—Officers wear gold stars on light gray shoulder boards or on shoulder straps (battle dress). Other ranks wear insignia on upper sleeve. Cap device: royal coat of arms on silver-edged red oval surmounted by gold crown and encircled by gold oak leaves.

General, Lieutenant General, and Major General:

Three (two, one) large stars.

Colonel and Lieutenant Colonel: Three (two) medium stars.

Major: Three small 5-pointed stars.

Captain: One small 3-pointed star between two small 5-pointed stars.

First Lieutenant and Lieutenant: Two (one) small 5-pointed stars.

Staff Sergeant, Sergeant, and Corporal: Four (three, two) light gray chevrons, points up.

Navy.—Admirals wear gold stripes around lower sleeve or silver stars (3, 2, 1) on gold mesh on shoulder boards. Other officers wear gold stripes on both. Upper stripes are looped. Warrant officers wear insignia on lower sleeve; petty officers on upper. Cap device: gold anchor on silver-edged red oval surmounted by gold crown and encircled by gold oak leaves.

Admiral, Vice Admiral, and Rear Admiral: Three (two, one) medium above one broad stripe.

Commodore: Four medium stripes.

Captain: One medium above one narrow and two medium stripes.

Commander: Three medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant and Sublieutenant: Two (one) medium stripes.

Chief Warrant Officer: One medium horizontal gold bar above one narrow gold bar.

Warrant Officer: One medium horizontal gold bar.

Petty Officer, 1st, 2d, and 3d class: Four (three, two) gold chevrons, points up.

Air Force.—Officers wear white-edged blue stripes around lower sleeve or on shoulder boards. Cap device: wings on silver-edged red oval surmounted by gold crown and encircled by gold oak leaves.

General, Lieutenant General, and Major General: Three (two, one) medium above one broad stripe.

Colonel: Four medium stripes.

Lieutenant Colonel: One medium above one narrow and two medium stripes.

Major: Three medium stripes.

Captain: One narrow between two medium stripes.

First Lieutenant and Second Lieutenant: Two (one) medium stripes.

FRANCE

Army.—Rank insignia of officers and warrant officers is worn on shoulder straps and on service and field caps; insignia of enlisted personnel is worn on the upper sleeve and on service and field caps. Regimental and corps insignia are colored tabs, worn by officers on coat lapels and on upper shirt sleeves, and by other ranks in the angle below chevrons. Regimental numbers are worn in the center of the tab.

Marshal of France: Seven silver stars. Around service cap, three rows of gold oak leaves.

General, Lieutenant General, and Major General:

Five (four, three) silver stars. Around service cap, two rows of gold oak leaves.

Brigadier General: Two silver stars. Around service cap, one row of gold oak leaves.

Colonel: Five gold (in some branches, silver) stripes, with space between upper two and lower three.

Lieutenant Colonel: Three gold alternating with two silver stripes (reversed in some branches).

Major: Four gold stripes, spaced one and three.

Captain, Lieutenant, and Sublieutenant: Three (two, one) gold stripes.

Warrant Officer, 1st and 2d class: On a gold (silver) stripe, a thin longitudinal red stripe.

Sergeant Major: Four gold chevrons, point up, with space between upper one and lower three.

Sergeant, 1st class: Three gold chevrons.

Sergeant: One red above one gold chevron.

Corporal, 1st class: One gold above two red chevrons.

Corporal and Private, 1st class: Two (one) red chevrons.

Navy.—Rank of officers and warrant officers is indicated by gold stripes around the lower sleeve of blue uniforms and on shoulder straps of other uniforms; petty officers and seamen wear insignia on the lower sleeve. Officers wear on the service coat shoulder a gold strap parallel to the sleeve seam, with width and amount of embroidery indicating grade. Officers wear around the cap band the same pattern of stripes worn on the sleeve. The cap device for all ranks is an anchor within a wreath, in gold.

Admiral: Five silver stars.

Vice Admiral Commanding Afloat: Four stars.

Vice Admiral and Rear Admiral: Three (two) stars.

Captain: Five gold stripes, with space between upper two and lower three.

Commander: Three gold alternating with two silver stripes, spaced as above.

Lieutenant Commander: Four gold stripes, spaced one above three.

Lieutenant, Lieutenant (junior grade), and Ensign: Three (two, one) gold stripes.

Warrant Officer, 1st and 2d class: Below one broad gold stripe, two (one) narrow stripes.

Chief Petty Officer; Petty Officer, 1st and 2d class: Three (two, one) diagonal gold stripes.

Leading Seaman, 1st class; Leading Seaman; and

Able Seaman: Three (two, one) diagonal red stripes.

Air Force.—Titles and rank insignia of officers and warrant officers are the same as for the army. On the blue service coat, officers wear the gold shoulder strap worn by the navy. On service and field caps all ranks wear a device of gold wings, above which general officers wear a pattern of five gold stars. Wings denoting flying rating are worn on the right breast pocket. Rank insignia for enlisted personnel, worn on shoulder straps, are as follows:

Master Sergeant: Three gold chevrons, point up, above one horizontal gold stripe.

Sergeant, 1st class; Sergeant (Professional); and Sergeant: Three (two, one) gold chevrons. *Corporal, 1st class*: One gold above two red chevrons.

Corporal and Private, 1st class: Two (one) red chevrons.

FEDERAL REPUBLIC OF GERMANY (WEST GERMANY)

Army.—Rank insignia of officers and sergeants major is worn on shoulder straps of all uniforms; other enlisted personnel wear chevrons on the upper sleeve. General officers wear gold edging on shoulder straps and on the coat collar above the lapel notch; other officers wear silver edging; sergeants major wear old-gold edging on collar only. General officers wear red lapel tabs with a gold laurel design. All ranks wear as an upper cap device the national yellow, red, and black rosette. The lower cap device consists of crossed sabers on a wreath of oak leaves, in gold for general officers, silver for other officers, and light bronze for enlisted personnel. General officers wear oak leaves on the cap visor. On the field cap the crossed sabers are worn without the wreath. All ranks wear branch insignia on the upper lapels of the service coat.

Lieutenant General, Major General, and Brigadier General: A semicircular wreath of four oak leaves below three (two, one) gold four-pointed stars.

Colonel, Lieutenant Colonel, and Major: Silver wreath below three (two, one) silver stars.

Captain, First Lieutenant, and Lieutenant: Three (two, one) silver stars.

Senior Staff Sergeant Major, Staff Sergeant Major, Senior Sergeant Major, and Sergeant Major: In old-gold metal, four (three, two, one) chevrons, point up, in pairs and singles. *Staff Sergeant and Sergeant*: Two (one) gold cloth chevrons, point up.

Senior Corporal, Corporal, and Private, 1st class: Three (two, one) diagonal gold stripes.

Navy.—Officers' rank is indicated by gold stripes around the lower sleeve of the blue service uniform and on shoulder boards of other uniforms; officers of the line wear a gold star above the sleeve stripes, but not on shoulder boards. Flag officers wear the same stripes on shoulder boards as on sleeves. Boatswains wear insignia on the lower sleeve, other enlisted ranks on the upper sleeve, in gold on blue uniforms and blue on white uniforms. The cap device is an anchor in a wreath of oak leaves, in gold, worn below the yellow, red, and black rosette. Flag officers wear oak leaves on the cap visor.

Officers' rank insignia of rank is the same as for the United States Navy, except *Commodore*, which is one narrow above one broad stripe. Rank insignia for enlisted personnel is as follows:

Senior Staff Boatswain, Staff Boatswain, Senior Boatswain, and Boatswain: Four (three, two, one) chevrons, point up, in pairs and singles. *Senior Petty Officers and Petty Officers*: Two (one) chevrons on upper sleeve. *Seaman, 1st, 2d, and 3d class*: Three (two, one) diagonal stripes on upper sleeve.

Air Force.—Titles and rank insignia of all personnel are the same as for the army, and the uniform is basically the same. All ranks wear around lower sleeves of service and field coats a blue band edged in silver on which is centered a pair of silver wings. The cap device, worn below the national rosette, is a pair of wings, in gold for general officers, silver for other officers, and light bronze for enlisted personnel, on a wreath of the same color on the service cap and without wreath on the field cap.

ITALY

Army.—Officers and warrant officers wear rank insignia on shoulder straps of all uniforms, and on tabs of shoulder-strap design on field caps. Noncommissioned officers wear insignia on the upper sleeve. All ranks wear on lapel tabs the national star, gold for general officers and silver for all others. Branch is indicated by color and shape of lapel tabs. The cap device for general officers is a spread eagle in a wreath; other personnel wear regimental or corps devices. The color and design of officers' chin straps indicates grade.

Lieutenant General, Major General, and Brigadier General: On blue-and-silver shoulder strap, three (two, one) gold stars edged in red.

Colonel, Lieutenant Colonel, and Major: On shoulder strap edged in gold braid, three (two, one) gold stars.

Captain, First Lieutenant, and Second Lieutenant: Three (two, one) gold stars.

Aiutante di Battaglia: On a red tab, three lines of gold braid radiating from button.

Warrant Officer, 1st, 2d, and 3d class: Three (two, one) lines of gold braid extending fanwise from shoulder strap button.

First Sergeant and Sergeant: Two (one) narrow below one broad gold chevron, point down.

First Corporal and Corporal: Same, in black.

Navy.—Officers' rank is indicated by gold stripes about $2\frac{1}{2}$ inches long on lower sleeve of blue uniforms and on shoulder boards of other uniforms, upper stripe forming a loop. Warrant officers wear insignia across the shoulder seam, petty officers on the upper sleeve. Officers, warrant officers, and chief petty officers wear on lapels the national star in silver and, as a cap device, an anchor within oak leaves surmounted by a three-turreted tower, in gold. Design of officers' chin straps indicates grade.

Vice Admiral of the Fleet, Vice Admiral, and Rear Admiral: Above a frieze design, three (two, one) medium stripes. On gold shoulder board, three (two, one) gold stars. *Captain, Commander, and Lieutenant Commander*:

Three (two, one) medium above one broad stripe.

Lieutenant, Lieutenant (junior grade), and Ensign: Three (two, one) medium stripes.

Warrant Officer, 1st, 2d, and 3d class: Three (two, one) gold bars interwoven with blue.

Chief Petty Officer, 1st and 2d class: Two (one) narrow below one broad gold chevron, point down.

Petty Officer: One broad above two narrow red chevrons.

Seaman, 1st class: One narrow red chevron.

Air Force.—Officers' rank insignia is identical with that of the navy except that the upper stripe forms a lozenge. Officers wear on the shoulders of the service coat a transverse strap with gold wings within a gold border. Insignia of warrant and noncommissioned officers is worn on shoulder straps. All ranks wear the national star in silver on upper lapels. The cap device is an eagle in a wreath surmounted by a three-turreted tower, in gold. Officers' gold chin straps vary in design indicating grade.

Officers' titles are as for the army, and rank insignia as for corresponding navy grades. Rank insignia of other personnel is as follows:

Aiutante di Battaglia: A silver star centered on three vertical gold bars, blue interwoven.

Warrant Officer, 1st, 2d, and 3d class: Three (two, one) vertical gold bars, blue interwoven.

First Sergeant and Sergeant: One broad above two (one) narrow gold chevrons, point down.

First Corporal and Corporal: One broad above two (one) narrow red chevrons.

REPUBLIC OF KOREA

Army.—Officers and warrant officers wear rank insignia on shoulder straps of all uniforms and on collar of shirt when worn as an outer garment. Enlisted rank insignia, undergoing change, was not yet standardized in 1956.

General, Lieutenant General, Major General, and Brigadier General: Four (three, two, one) silver stars.

Colonel, Lieutenant Colonel, and Major: Three (two, one) silver nine-petaled bamboo blossoms.

Captain, First Lieutenant, and Second Lieutenant: Three (two, one) silver diamonds.

Warrant Officer: One gold diamond.

Navy.—Rank of officers is indicated by gold stripes around the lower sleeve of blue uniforms and on shoulder boards. Number of stripes is the same as for the United States Navy, but without the gold star. On shirt collars and field uniforms, officers and warrant officers wear metal insignia as for the army. Rank insignia for enlisted personnel, worn on the upper sleeve, is as follows:

Chief Petty Officer: Three chevrons, point down, below one narrow arc.

Petty Officer, 1st, 2d, and 3d class: Three (two, one) chevrons.

Seaman, 1st and 2d class, and Apprentice Seaman: Three (two, one) horizontal bars.

Air Force.—Titles and rank insignia of officers and warrant officers are the same as for the army. Enlisted insignia is undergoing change.

NETHERLANDS

Army.—Rank insignia of officers and warrant officers is worn on lapel tabs of service and battle dress, that of other ranks on the upper left sleeve. Officers wear branch insignia on shoulder straps; other ranks, on cap and beret. A gold national emblem is the officers' cap device and is also worn by all ranks as a flash on the upper left sleeve.

General: On gold-edged red lapel tab, crossed gold batons above four silver stars in square.

Lieutenant General: Four silver stars in square.

Major General: Two silver above two gold stars.

Colonel, Lieutenant Colonel, and Major: On red tab, below horizontal gold stripe, three (two, one) silver stars.

Captain, First Lieutenant, and Second Lieutenant: Three (two, one) silver stars.

Warrant Officer: One round silver button.

Sergeant Major: Two gold-bullion chevrons, point up.

Sergeant, 1st class: One gold-bullion chevron below one half-width chevron.

Sergeant: One gold-bullion chevron.

Corporal, 1st class, and Corporal: Two (one) chevrons of gold cloth.

Private, 1st class: One red chevron.

Navy.—Officers' rank is indicated by gold stripes around the lower sleeve of blue uniforms and on shoulder boards of other uniforms, the upper stripe forming a loop. Petty officers and seamen wear insignia on the upper sleeve. Officers wear on upper lapels an anchor below a crown, in gold. Officers' cap device is an anchor within oak leaves below a crown, in gold; for petty officers, the same without oak leaves. Flag officers wear two rows of gold braid on cap visors, senior officers one row.

Lieutenant Admiral, Vice Admiral, and Rear Admiral: One medium above one broad stripe, surmounted by four (three, two) silver stars.

Commodore: One broad stripe.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant: Two medium stripes.

Lieutenant (junior grade): One medium above one narrow stripe.

Ensign: One medium stripe.

Chief Petty Officer: Four gold chevrons, point down.

Petty Officer, 1st and 2d class: Three gold chevrons (same for both classes).

Petty Officer, 3d class: Two gold chevrons.

Seaman, 1st and 2d class: Two (one) red chevrons.

Air Force.—Titles and rank insignia of all personnel are the same as for the army. The cap device is a soaring eagle in an oak-leaf wreath below a crown, in gold. General officers and colonels wear gold laurel leaves on cap visor; other field officers wear a gold stripe along visor edge. Gold rating badges are worn over the left breast pocket. Chevrons of sergeants are silver-gray; of corporals, white.

NORWAY

Army.—Officers' rank insignia is worn on lapel tabs of service uniforms and on shoulder

straps of battle dress; insignia of other ranks is worn on the upper sleeve. Cap device for all ranks is a red, white, and blue rosette above the royal emblem in gold on a red disk for officers and on a brown disk for other ranks; these devices are connected by strips of different pattern, indicating grade. Device for battle-dress beret is the royal monogram below a crown, encircled by an oak-leaf wreath, in silver. Branch is indicated by rectangular colored flashes high on upper sleeves.

General, Lieutenant General, and Major General:

On lapel tab or shoulder strap of gold oak-leaf design, three (two, one) silver stars.

Colonel, Lieutenant Colonel, and Major: On tab or strap edged with a silver stripe, three (two, one) silver stars.

Captain, Lieutenant, and Sublieutenant: Three (two, one) silver stars, plain tab or strap.

Master Sergeant: Three chevrons, point up, above a crown.

Sergeant, Corporal, and Private, 1st class: Three (two, one) chevrons.

Navy.—Officers' rank is indicated by gold stripes around lower sleeve or on shoulder boards, upper stripe forming a loop. Chief petty officers wear insignia on lower sleeve, petty officers on extreme upper sleeve. Cap device for officers is an anchor within oak leaves below a crown, in gold; for petty officers, same without oak leaves.

Admiral, Vice Admiral, and Rear Admiral: A broad stripe with one medium stripe below and three (two, one) medium stripes above.

Commodore: Three medium above one broad stripe.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant and Lieutenant (junior grade): Two (one) medium stripes.

Chief Petty Officer, 1st and 2d class: Two (one) gold chevrons, point up.

Petty Officer, 1st, 2d, and 3d class: Below a red anchor and crown device, three (two, one) diagonal red stripes.

Seaman, 1st class: On lower sleeve, a red crown.

Air Force.—Titles and rank insignia for all personnel are the same as for the army. Officers' cap device is a red, white, and blue rosette within oak leaves, surmounted by spread wings below a crown, in silver; cap devices for other ranks are as for the army. Rating badges in silver are worn over right breast pocket.

PORTUGAL

Army.—Officers' rank insignia is worn on the lower sleeve of service dress and on the shoulder straps of battle dress; insignia of other ranks is worn on upper sleeve and shoulder straps. Branch is indicated by cap devices for all ranks and by colored collar tabs for officers.

Lieutenant General, Major General, and Brigadier: Four (three, two) silver stars.

Colonel, Lieutenant Colonel, and Major: Three (two, one) narrow gold stripes, $2\frac{1}{2}$ inches long, above one broad stripe.

Captain, Lieutenant, and Sublieutenant: Three

(two, one) narrow gold stripes.

Warrant Officer: Coat of arms in gold wreath.

First Sergeant and Sergeant: Four (three) gold chevrons, point up.

First Corporal: Three gold chevrons, point down.

Corporal and Private, 1st class: Two (one) black chevrons edged in white, point up.

Navy.—Officers' rank is indicated by gold stripes around lower sleeve and on shoulder boards, upper stripe forming a loop. Warrant officers wear insignia on lower sleeve, other ranks on upper sleeve. Cap device for officers and petty officers is a silver anchor within gold oak leaves below gold coat of arms.

Admiral and Vice Admiral: Above one broad stripe, two (one) medium stripes.

Rear Admiral: One broad stripe.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant and Sublieutenant: Two (one) medium stripes.

Warrant Officer: Coat of arms in gold wreath.

Chief Petty Officer and Petty Officer, 1st class: Four (three) gold chevrons, point up.

Petty Officer, 2d class: Three gold chevrons, point down.

Petty Officer, 3d class, and Seaman, 1st class: Two (one) red chevrons, point up.

Air Force.—Titles and rank insignia of all ranks are the same as for the army. Cap device is the coat of arms within gold oak leaves. Gold rating badges are worn above left pocket.

SWITZERLAND

Army.—Officers' rank insignia is worn on shoulder straps of service and field uniforms, on field-cap tabs, and around service cap. Insignia of other ranks is worn on upper sleeve. Branch is indicated by color and design of lapel tabs; unit numbers are worn on shoulder straps of branch color. Enlisted specialist ratings are worn above chevrons. Gold rating badges, including flying ratings (the air force is part of the army), are worn above left pocket.

General: On gold-edged black background, four silver stars on row of gold leaves. Around service cap, on black background, broad band of gold leaves above a medium band and below a narrow band.

Colonel Commanding Corps: On same background, three stars. Around service cap, one broad between two narrow bands of gold leaves.

Colonel Commanding Division: Same background with two stars. Around service cap, one broad below one narrow band of gold leaves.

Colonel Brigadier: Same background with one star. Around service cap, one broad band of leaves. Colonel brigadiers not in command wear the same without black background.

Colonel, Lieutenant Colonel, and Major: Three (two, one) broad gold stripes.

Captain, First Lieutenant, and Lieutenant: Three (two, one) narrow gold stripes.

Warrant Officer: One gold chevron (point up) above and two chevrons below a gold cross within gold wreath.

Sergeant Major: Two chevrons below same device.

TURKEY

Army.—Officers wear rank insignia on shoulder straps, other personnel on the upper sleeve. Officers' cap device is a crescent, points up, with star between points, within oak-leaf wreath, in gold. General officers wear two rows of gold braid on cap visor; senior officers wear one row. Branch is indicated by colored lapel tabs and by enlisted men's cap devices.

Field Marshal: On gold tab on red shoulder strap, crescent and star on crossed batons.

General: On gold-edged shoulder strap, the same.

Lieutenant General, Major General, and Brigadier General: On plain shoulder strap, the same device below three (two, one) gold stars.

Colonel, Lieutenant Colonel, and Major: Crescent and star below three (two, one) stars.

Captain, First Lieutenant, and Second Lieutenant: Three (two, one) gold stars.

Master Sergeant: Four gold chevrons, point down, with gold crescent and star in angle above.

First Sergeant, Staff Sergeant, Sergeant, and Corporal: Four (three, two, one) chevrons.

Navy.—Officers' rank is indicated by gold stripes around lower sleeve and on shoulder boards, upper stripe forming a loop; insignia of other ranks is worn on upper sleeve. Cap device for officers is an anchor on blue oval in wreath below crescent and star, in gold; for petty officers, anchor on oval below gold knot, surmounted by gold crescent and star. Flag officers wear two rows of gold braid on cap visor; senior officers, one row.

Admiral of the Fleet: Four medium stripes above one broad stripe.

Admiral: From the top: one medium, one narrow, two medium, and one broad stripe.

Vice Admiral, Rear Admiral, and Commodore: Three (two, one) medium above a broad stripe.

Captain: Four medium stripes.

Commander: One narrow below one medium and above two medium stripes.

Lieutenant Commander and Commander Lieutenant: Three (two) medium stripes.

Lieutenant: One medium above one narrow stripe.

Lieutenant (junior grade): One medium stripe.

Ensign: One narrow stripe.

Chief Petty Officer: Four gold chevrons, point down, below gold crescent and star in angle.

Petty Officer, 1st and 2d class; Leading Seaman; and Seaman, 1st class: Four (three, two, one) gold chevrons.

Seaman, 2d class: Plain upright gold anchor.

Air Force.—Titles and rank insignia are as for the army. Cap device is also the same, but with a soaring eagle superimposed on crescent.

Silver rating wings with crescent and star in center are worn over left breast pocket.

UNION OF SOVIET SOCIALIST REPUBLICS

Army.—Officers' rank insignia is worn on

shoulder boards, collar patches, and coat cuffs. Other ranks wear insignia on shoulder boards and collar patches. On the cap, general officers wear a large red star on gold disk; all other ranks wear a red star only. Gold collar-patch ornamentation consists of oak leaves for marshals, laurel leaves for generals, two horizontal bars with zigzag lines for field officers, one such bar for company officers, and one plain bar for non-commissioned officers. Gold cuff ornamentation for marshals and generals is a band of oak and laurel leaves respectively; field officers, two vertical pillars; company officers, one pillar. Branch is indicated by color of shoulder boards and collar patches, and by metal shoulder board devices. Personnel of technical branches wear silver ornamentation.

General officers wear gold or silver shoulder boards for service and olive drab for field, edged in red (magenta for service branches). Field officers wear gold or silver service shoulder boards, edged and with two longitudinal stripes in branch color; field shoulder boards are olive drab edged in branch color with two stripes in claret (brown for service branches). Company officers' shoulder boards are the same with one central stripe only. Other ranks wear service shoulder boards in branch color, field shoulder boards of olive drab; metal branch insignia is worn on service shoulder boards only. Enlisted ranks are indicated by transverse gold or silver stripes on service shoulder boards and claret stripes on field shoulder boards.

Marshal of the Soviet Union: A very large silver star below the national coat of arms.

Chief Marshal: Large silver star within silver oak-leaf wreath, below branch insignia.

Marshal: Large silver star below branch insignia.

General, Lieutenant General, Major General, and Brigadier General: Four (three, two, one) small silver stars.

Colonel, Lieutenant Colonel, and Major: On two-stripe shoulder boards, three (two, one) silver stars, below branch insignia.

Captain, Senior First Lieutenant, First Lieutenant, and Second Lieutenant: On one-stripe shoulder boards, four (three, two, one) silver stars, below branch insignia.

Master Sergeant: One broad stripe intersected by a narrow longitudinal stripe.

Sergeant 1st Class: One broad stripe.

Sergeant, Corporal, and Private, 1st class: Three (two, one) narrow stripes.

Navy.—All personnel wear rank insignia on shoulder boards of all uniforms. Line officers also wear gold stripes around lower sleeve of blue uniforms, with gold star above stripes (flag officers, large gold star surmounting hammer and sickle). Various corps are indicated by shoulder board colors and metal insignia.

Line officers' sleeve stripes are the same as for the United States Navy, except lieutenant commander (one narrow above two medium stripes). Shoulder board insignia is as follows:

Admiral of the Fleet: On gold shoulder board, a large silver star with anchor in red center.

Admiral, Vice Admiral, and Rear Admiral: Same, with three (two, one) small silver stars.

Commodore, Captain, and Commander: On gold shoulder board with two longitudinal stripes in corps color, three (two, one) silver stars.

Lieutenant Commander, Lieutenant, Lieutenant (junior grade), and Ensign: On same with one stripe, four (three, two, one) silver stars.

Warrant Officer: On shoulder board in corps color, a broad gold transverse stripe intersected by a narrow longitudinal stripe.

Chief Petty Officer: One broad gold stripe.

Petty Officer, 1st and 2d class, and Seaman, 1st class: Three (two, one) narrow gold stripes.

Air Force.—Titles and rank insignia are as for the army, with sky-blue as branch color. As officers wear a roll-collar coat, the metallic device of a vertical propeller centered on horizontal wings is worn on lapel tabs.

UNITED KINGDOM

Army.—Rank insignia is worn by officers on shoulder straps, by warrant officers on lower sleeve, and by other ranks on upper sleeve. General officers wear red lapel tabs with vertical gold laurel stripe, brigadiers and colonels with black braid stripe. Other officers wear regimental or corps devices on lapels. Colonels and above wear a red band around the cap. Cap device for field marshals is crossed red batons on gold laurel wreath, surmounted by lion atop crown; general officers, same with crossed baton and sword; brigadiers and colonels, crown surmounted by lion. Other officers wear regimental or corps devices.

Field Marshal: Crossed red batons on gold laurel wreath surmounted by gold crown.

General: Crossed gold sword and baton below a four-pointed gold star below a gold crown.

Lieutenant General and Major General: Crossed sword and baton below gold crown (gold star).

Brigadier, Colonel, and Lieutenant Colonel: Below a gold crown, three (two, one) gold stars.

Major: A gold crown.

Captain, Lieutenant, and Second Lieutenant: Three (two, one) gold stars.

Warrant Officer, class I: Gold coat of arms.

Warrant Officer, class II: Gold crown in wreath.

Staff Sergeant: Three chevrons, point down, with gold crown in the upper angle.

Sergeant, Corporal, and Lance Corporal: Three (two, one) chevrons.

Navy.—Officers' rank is indicated by gold stripes around lower sleeve of blue uniforms, the upper stripe forming a loop, and on shoulder boards of other uniforms. Non-line officers wear colored backing in corps color between stripes. Chief petty officers wear insignia on lower sleeve, petty officers and seamen on upper left sleeve only. Flag officers wear two rows of gold leaves on cap visor; captains and commanders, one row. Officers' cap device is a silver anchor within gold wreath below a red-backed gold crown; chief petty officers, a silver anchor within gold ring within gold wreath below a red-backed gold crown; petty officers, the same without wreath.

Admiral of the Fleet: Four medium stripes above a broad stripe. On gold shoulder board, crossed batons on laurel wreath below royal monogram, in silver, surmounted by gold crown.

Admiral, Vice Admiral, and Rear Admiral: Three (two, one) medium stripes above a broad stripe. On gold shoulder board, three small (two small, one large) silver stars below crossed sword and baton surmounted by gold crown.

Commodore: One broad stripe.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant and Sublieutenant: Two (one) medium stripes.

Warrant Officer: One narrow stripe.

Chief Petty Officer: Three gold buttons.

Petty Officer: Crossed red anchors below crown.

Leading Seaman: Upright red anchor.

Titles and rank insignia for the Royal Marines are as for the army. The letters "RM" in gold are worn on outer edge of shoulder straps. Cap device is a silver hemisphere within gold wreath, on red background, surmounted by lion atop crown in gold.

Air Force.—Officers' rank is indicated by blue stripes, edged in black, around lower sleeve of service coat and on shoulder straps of other uniforms. Warrant officers wear insignia on lower sleeve, other ranks on upper sleeve. Cap device for grades of air marshal is a soaring eagle within wreath surmounted by lion atop crown, in gold; for other officers, soaring eagle above laurel spray and below crown, in gold; for other ranks, the letters "RAF" within wreath below crown, in gold. Flying rating badges are worn above left breast pocket.

Marshal of the Royal Air Force, Air Chief Marshal, Air Marshal, and Air Vice Marshal: Four (three, two, one) medium stripes above one broad stripe.

Air Commodore: One broad stripe.

Group Captain and Wing Commander: Four (three) medium stripes.

Squadron Leader: One narrow between two medium stripes.

Flight Lieutenant and Flying Officer: Two (one) medium stripes.

Pilot Officer: One narrow stripe.

Warrant Officer, class I: Coat of arms.

Warrant Officer, class II: Crown within wreath.

Flight Sergeant: Three blue chevrons, point down, below gold crown.

Sergeant and Corporal: Three (two) chevrons.

Senior Aircraftman: Three-bladed propeller.

Leading Aircraftman: Horizontal two-bladed propeller.

Chief Technician: Three chevrons, point up, below gold crown.

Senior Technician, Corporal Technician, and Junior Technician: Three (two, one) chevrons, point up.

UNITED STATES

Army.—Officers' rank insignia is worn on shoulder straps of service, semidress, and dress uniforms, on lower sleeve of mess and evening dress uniforms, and on collar of shirt when worn as outer garment. The dress-uniform shoulder strap, worn parallel to the sleeve seam, is gold-bordered with backing and trim in branch colors; officers below colonel wear pairs of insignia thereon. General officers of the line wear rank insignia on both sides of shirt collar; other officers wear rank insignia on right and branch insignia on left; warrant officer insignia is worn on left. Officers and warrant officers wear rank insignia on left side of garrison cap. Enlisted personnel wear rank insignia on upper sleeve.

Cap device for officers is the United States coat of arms in gold; for enlisted personnel, a smaller coat of arms on a disk. Warrant officers wear on cap and lapel a wreath superimposed on a spread eagle, in gold.

General of the Army: Five silver stars in a circle below the national coat of arms in gold and colored enamel.

General, Lieutenant General, Major General, and Brigadier General: Four (three, two, one) silver stars.

Colonel: Silver spread eagle.

Lieutenant Colonel: Silver oak leaf.

Major: Gold oak leaf.

Captain: Two silver bars.

First Lieutenant: One silver bar.

Second Lieutenant: One gold bar.

Chief Warrant Officer W-4 and W-3: A brown enamel bar edged in silver with two (one) transverse silver stripes.

Chief Warrant Officer W-2 and Warrant Officer W-1: brown enamel bar edged in gold with two (one) transverse gold stripes.

Sergeant Major, First Sergeant, and Master Sergeant: Three chevrons, point up, above three descending arcs, with centered star (diamond, blank).

Sergeant 1st class and Staff Sergeant: Three chevrons above two (one) arcs.

Sergeant, Corporal, and Private 1st class: Three (two, one) chevrons.

Specialist Nine and Specialist Eight: Three ascending arcs above two (one) chevrons, point down, with centered eagle and shield.

Specialist Seven, Six, Five, and Four: Above the eagle and shield three (two, one, no) arcs.

On blue and white mess uniforms, officers' rank is indicated by the number of rows of an ornamental knot on lower sleeve; general officers wear a band of oak leaves on a velvet stripe below silver stars of grade. On evening dress, metal rank insignia is worn within a single ornamental knot on lower sleeve. On service and dress caps, field and general officers wear gold oak leaves on visor; on blue dress cap, general officers also wear gold oak leaves around cap band.

On upper lapels of service and dress coats officers wear the letters "US" in gold; on lower lapels, branch insignia. Insignia for enlisted personnel is similar, but mounted on gold disks. The various branch insignia, and colors which determine dress-uniform trim and garrison-cap piping (enlisted personnel), are as follows:

Adjutant General's Corps: Red, white, and blue enameled shield; dark blue and scarlet.

Armor: M-26 tank on crossed sabers; yellow.

Artillery: Crossed cannons and missile; scarlet.

Chaplains: Christian, Latin cross; Jewish, Star of David above Mosaic tablets; black.

Chemical Corps: Benzene ring centered on crossed retorts; cobalt blue and golden yellow.

Corps of Engineers: Castle; scarlet and white.

Finance Corps: Diamond; silver gray and golden yellow.

General Staff: United States coat of arms on silver star; gold and black.

Infantry: Crossed muskets; light blue.

Inspector General's Department: Crossed sword and fasces wreathed; dark blue and light blue.

Judge Advocate General's Corps: Crossed sword and pen wreathed; dark blue and white.

Medical Service: Medical Corps has plain caduceus; other corps (such as *Dental, Nurse*), have superimposed letters; maroon and white.

Military Police Corps: Crossed pistols; yellow and green.

National Guard Bureau: Crossed fasces superimposed on eagle; dark blue.

Ordnance Corps: Flaming bomb; crimson and yellow.

Professors, United States Military Academy: On shield, helmet of Pallas on Greek sword, below eagle and scroll; scarlet and silver gray.

Quartermaster Corps: Crossed sword and key on wheel surmounted by an eagle; buff.

Signal Corps: Flaming torch centered on crossed signal flags; orange and white.

Transportation Corps: On ship's wheel, winged wheel on shield; brick red and golden yellow.

Women's Army Corps: Helmeted head of Pallas Athene; old gold and moss green.

Navy.—Rank of officers and warrant officers is indicated by gold stripes around lower sleeve of blue uniforms and on shoulder boards of other uniforms. Line officers wear a gold star above stripes; other officers, gold corps devices; warrant officers, specialist rating devices. Rank insignia and specialist ratings of petty officers and seamen are worn on upper sleeve. With some uniforms, officers wear on shirt collar metal rank insignia identical with that of the army; line officers on both sides of collar, other officers rank insignia on right and corps insignia on left. Warrant officers' metal insignia is the same as for the army, with background in blue instead of brown. Cap device for officers is a silver shield on crossed gold anchors below silver spread eagle; for warrant officers, crossed gold anchors; for chief petty officers, an upright gold anchor with letters "USN" across shank. Flag officers wear two rows of gold oak leaves on cap visor, captains and commanders wear one row.

Fleet Admiral: Four medium stripes above one broad stripe. On gold shoulder board, five silver stars in circle below silver foul anchor.

Admiral, Vice Admiral, and Rear Admiral: Three (two, one) medium stripes above one broad stripe. On gold shoulder board, four (three, two) silver stars below silver foul anchor.

Commodore: One broad stripe. On gold shoulder board, one silver star below silver anchor.

Captain and Commander: Four (three) medium stripes.

Lieutenant Commander: One narrow between two medium stripes.

Lieutenant: Two medium stripes.

Lieutenant (junior grade): One narrow above one medium stripe.

Ensign: One medium stripe.

Chief Warrant Officer W-4, W-3, and W-2: One medium stripe with one (two, three) square blue tabs superimposed thereon.

Warrant Officer W-1: Narrow stripe, three tabs.

Master Chief Petty Officer, Senior Chief Petty Officer, and Chief Petty Officer: Three chevrons, point down, below ascending arc enclosing specialist rating, surmounted by eagle and two (one, no) stars.

Petty Officer, 1st, 2d, and 3d class: Three (two, one) chevrons below rating and eagle.

Seaman, Seaman Apprentice, and Seaman Recruit: Three (two, one) diagonal white (blue) stripes.

Insignia worn above stripes and on collars by officers of the various corps is as follows:

Medical Corps: Silver acorn on gold oak leaf (with variations for other medical services).

Supply Corps: Spray of three gold oak leaves.

Civil Engineer Corps: Four gold oak leaves and two silver acorns, in diamond pattern.

Chaplains: Christian, gold Latin cross; Jewish, gold Star of David above Mosaic tablets.

Marine Corps.—Titles and rank insignia of officers are the same as for the army. The one exception is that there is no General of the Marine Corps. Warrant officers also wear similar insignia, with red instead of brown background. Cap device for all personnel is a half globe portraying the Western Hemisphere, pierced diagonally by a foul anchor, surmounted by a spread eagle; this device is worn in bronze with service uniform, in silver with officers' dress uniform, and in gold with enlisted men's dress uniforms. All personnel wear the same device on garrison cap and on lapels of service and dress coats.

Insignia of rank of enlisted personnel, worn on the upper sleeve is as follows:

Sergeant Major and Master Gunnery Sergeant: Three chevrons, point up, above four descending arcs, with centered star (bursting bomb).

First Sergeant and Master Sergeant: Three chevrons above three arcs, with centered diamond (crossed rifles).

Gunnery Sergeant and Staff Sergeant: Three chevrons above two (one) arcs, with crossed rifles.

Sergeant, Corporal, and Lance Corporal: Three (two, one) chevrons above crossed rifles.

Private 1st class: One chevron.

Air Force.—Titles and rank insignia of officers are as for the army, warrant officers' bars having a light blue background. The one exception is for the General of the Air Force; the national coat of arms is omitted from that insignia. Cap device for both officers and warrant officers is the same as for army officers, but of oxidized silver; for airmen, a smaller device encircled by a ring. General officers wear around capband and on visor a pattern of clouds and lightning bolts in aluminum braid; colonels, on visor only. Officers wear the letters "US" in oxidized silver on upper coat lapels, airmen the same encircled by a ring. On the shirt collar, officers and warrant officers wear rank insignia slightly smaller than on the coat.

Chief Master Sergeant and Senior Master Sergeant: Three chevrons, point down, on which is centered a star on circular background, above three descending arcs, the whole surmounted by two (one) shallow chevrons, point up.

Master Sergeant, Technical Sergeant, and Staff Sergeant: Three chevrons and star above three (two, one) arcs.

Airman, 1st, 2d, and 3d class: Three (two, one) chevrons and star.

Coast Guard.—Titles and insignia of rank of all personnel are the same as those of the navy, the highest commissioned grade being that of admiral. In lieu of the navy gold star, officers wear the silver Coast Guard shield above the upper stripe on blue uniforms and on the shoulder

board of other uniforms; flag officers wear the shield superimposed on the shoulder board foul anchor. Warrant officers wear the shield between sleeve stripe and specialist insignia; petty officers and seamen wear the shield on the lower sleeve. The cap device for officers and chief warrant officers is the silver shield superimposed on a gold spread eagle holding a horizontal silver anchor in its talons; for warrant officers, the silver shield superimposed on crossed gold foul anchors; for chief petty officers, the silver shield superimposed on an upright gold anchor.

ARTHUR P. WADE,
Lieutenant Colonel, United States Army.

INSOLVENCY, ĭn-sŏl'vĕn-sĭ. In a popular sense the word "insolvency" applies only to persons without property of means sufficient to satisfy their creditors. The legal definition embraces all who are unable to pay their debts at maturity in the ordinary course of business, even though they may possess assets exceeding their liabilities. A failure to meet overdue obligations renders a person liable to proceedings against him in a court of insolvency, in which his assets may be taken into the possession of the officers, marshaled, and distributed to his creditors. Should there be an amount in excess of what is required to pay the creditors and the expenses of administration, the balance so remaining is the property of the debtor. From a very early period in the history of civil government, laws have existed providing for proceedings by creditors against insolvent debtors, by which the debtor's property could be taken from his possession, to be held by another as a trust fund to be applied to the payment of his just debts. In case of an insufficient amount to pay all debts in full, provisions are usually made for a pro rata distribution. These laws have generally provided for classes of preferred debts, payments of which were to be made in full, even though such payments exhausted the entire assets. Preferred claims commonly included all claims of the government or state, and often claims for labor to a limited amount, and claims for the necessities of life. Provisions are usually made for the exemption of certain articles to the use of the debtor, not to be included in the assets. The Constitution of the United States provides that Congress may establish uniform laws on the subject of bankruptcy throughout all the states. A uniform national law upon the subject now exists. See also **BANKRUPTCY LAWS**.

INSOMNIA, ĭn-sŏm'nĭ-ă, a disordered condition of the body characterized by sleeplessness, trouble in going to sleep, or awakening after only a few hours. Many victims of insomnia attribute their sleep problems to such things as noise, light, or an uncomfortable bed. These factors can cause some insomnia, but a person in good physical and mental health is not bothered long by them. Among the more serious causes of sleeplessness are mental or emotional problems which keep the victim under such tension that he is unable to relax. This type of tension often creates real physical disorders which cause discomfort and thus may interfere with sleep. Insomnia then becomes a psychosomatic problem, and some degree of psychotherapeutic treatment is needed in conjunction with the physician's efforts to cure the bodily disorder of the sufferer.

Less severe cases of insomnia usually respond to such treatment as warm baths before retiring, or hot food, or anything which will promote easing of muscular tension. Sedative pills should only be used after a physician has prescribed them; they cannot safely be used for any extended period of time and do not attack the causes of insomnia, although they may succeed in bringing sleep quickly.

INSPECTOR or INSPECTOR GENERAL, in-spēk'tēr, a staff officer in the armed forces of a nation. Inspectors general are usually assigned to higher units, installations, and organizations—those commanded by general officers or their naval or air force counterparts. Usually only the chief inspector general in each service holds general officer or equivalent rank. Inspectors general may be members of an established inspector general's department, or they may be other officers temporarily designated. The duties of inspectors general encompass almost every phase of military affairs. They maintain surveillance over: (1) the overall military efficiency and economy; (2) the discipline, conduct, living conditions, training, and morale of individuals and units; (3) the condition of installations, arms, and equipment; (4) the economical and lawful expenditure of funds; and (5) the proper utilization and care of property. In addition, they investigate complaints concerning individuals and conditions, and they conduct special investigations ordered by their superiors. Inspectors general report their findings to the appropriate headquarters with recommendations for corrective action.

VINCENT J. ESPOSITO,
Colonel, United States Army.

INSPIRATION, in-spi-rā'shūn, literally "in-breathing," by God or His Spirit, which enabled a person (for example, a prophet) to utter divine truth or predict the future. It is a state which accompanies or precedes, and explains, the imparting of divine revelation. In Genesis 2:7, divine inbreathing was the mode by which life was imparted to the first man, a view which presupposes the physical reality of "spirit" or the "breath of life." The term was especially appropriate to describe the seizure of a prophet (Hebrew *nabi*), who thereupon spoke words not his own but presumably from God or a "spirit." This state was also known in Greek religion and in cults elsewhere in the ancient world. The term "enthusiasm" (*enthousiasmos* or *entheos*) explained it, as in the worship of Dionysus (consult Euripides' *Bacchae*, lines 298 ff.), the oracular responses of the Pythia at Delphi, and Plato's description of poetic inspiration (*Ion*, sects. 533D-534). Virgil's *Aeneid* (Book VI, lines 43-54, 77-80, 98-101) gives a classic description of inspiration according to the usual Hellenistic conception: the sibyl is helpless under the powerful seizure by Apollo (consult also Lucan, Book V, lines 161-197; Ovid's *Fasti*, Book VI, lines 535-540). After the 4th century B.C., this primitive conception was revived and became increasingly popular. The later books of the Bible do not assume this cataleptic type of inspiration, except in Acts 2:1-4, where speaking with "other tongues" is interpreted as foreign languages, and I Corinthians 12-14, where Paul reproves the speaking with tongues (*glossolalia*) as unedifying. Instead, it is assumed that reason and self-control must prevail: "the spirits of prophets are subject to prophets" since "God is

not a God of confusion but of peace" (I Corinthians 14:32-33).¹

If we view the Bible as a whole and also take into account the later development of Christian theology, it is clear that three stages of thought are reflected: the inspiration of (1) men or women; (2) their words; and (3) the written record of their words. The basic, fundamental idea is the inspiration of the living man, especially of the prophet; the concept reflects prophetic experience. The New Testament claims a high level of inspiration for the Old Testament writings (Mark 12:36; Matthew 15:4, 1:22; Acts 1:16). The Old Testament contains the "oracles of God" (Romans 3:2, 9:25; I Peter 1:10-12, 4:11; Hebrews 1:1; II Peter 1:21; II Timothy 3:16-17). Like other apocalyptic works, Revelation makes strong claims for inspiration (see 1:3; 10:7, 11; 22:6-9, 18-19, concerning the message; and 1:10; 4:2; 17:3; 21:10, concerning the seer himself and the method of inspiration). Here the later idea of inspiration as ability to predict the future is the main consideration. Similar ideas of inspiration, but with more emphasis on the discernment of divine truth, are found in Philo of Alexandria; consult *On Preliminary Studies*, chap. 24, -sects. 131-136; *On the Special Laws*, Book IV, chap. 8, -sects. 48-52; and compare Flavius Josephus, *Antiquities of the Jews*, Book IV, chap. 6, par. 5, -sects. 118-125.

The constant use of the Old Testament encouraged both Jews and Christians to view their sacred books as inspired. Toward the end of the 2d century A.D. the self-styled prophet Montanus and his followers in Phrygia revived the primitive notion of direct inspiration and predicted the coming of the New Jerusalem (consult Eusebius of Caesarea, *Historia Ecclesiastica*, Book V, chap. 16). Such so-called prophecy has been found in many later centuries. Against it the church has appealed to the Scriptures as final. The Council of Florence (1431-1445) insisted that both Testaments are inspired by the same Holy Spirit; the Vatican Council (1869-1870) stated that "God is the author of sacred scripture." While recognizing that the Bible contains differences in order in relating events and also different levels of inspiration, Martin Luther held that no soul would be lost or saved either by such difficulties or by their solution (consult his *Exposition* of I John 1-2 and 18 in the Erlangen edition of his works, vol. 46, p. 174, and vol. 50, pp. 308 f.). John Calvin insisted that the Scriptures form a unity, without distinction in meaning between the two Testaments; the revealed truth may be recognized by the inner voice which speaks through the Scriptures and awakens the spirit of man—the *testimonium Sanctus Spiritus internum* or *interior Spiritus Sancti persuasio* (*Institutes of the Christian Religion*, 1536, Book I, chap. 36).

Various theories of inspiration have been held, all the way from divine dictation (Athenagoras, *Apology*, Book IX: "like a flute"; compare Epiphanius, *Heresies*, 48:4, against Montanus; compare Plato, *Timaeus*, 71E f.), including even the punctuation (so the *Formula Consensus Helvetica*, 1675), to modern liberal views which recognize inspiration in all deeply moving or illuminating literature or music. *Plenary* inspiration assumes the inspired utterance to cover every subject, even nonreligious; *literal* or *verbal*, that of every word and letter.

The chief objections that have been raised to

¹ Revised Standard Version.

extreme theories of verbal inspiration include: (1) the existence of "self-contradictions" within the Bible, as in parallel stories of the same events; and (2) the existence of lower levels of religious and ethical teaching, as in I Samuel 15; Psalm 137:8f.; Numbers 15:32-36. These are both features of ancient religious tradition which can be explained only on a historical view of its origin and transmission. Other objections to verbal inspiration theories include: (1) the uncertainty of the original text in some passages, a problem which can scarcely be solved by selecting one manuscript as infallible, since most early manuscripts are incomplete; (2) the diversity in the translations, even the ancient ones, so that the verbal inspiration has evidently failed to carry over to the Scriptures actually used by the church in later centuries; and (3) the uncertainty of the meaning of some words in Hebrew and Greek and the inevitable alterations which have taken place in most of them as languages have grown and changed. Most Christians now probably hold that the Bible is inspired in the sense of *inspiring*; as Samuel Taylor Coleridge believed (*Confessions of an Inquiring Spirit*, 1840, quoting Wisdom 7:27), we recognize as inspired what "finds" us in our inmost hearts.

FREDERICK C. GRANT.

INSTALLMENT BUYING AND SELLING, in-stōl'mēnt, a system of trading in which the purchaser makes periodic partial payments over a number of weeks, months, or years. The item purchased is usually a consumer good bought at retail. However, purchases may be made at wholesale, and manufacturers' goods are occasionally included. An installment purchase, therefore, involves the extension of credit to the purchaser. The installment payments include interest and service charges, as well as periodic repayments of principal.

A distinction must first be made between installment loan credit and installment sales credit. An installment loan involves the advance of money by a lender to the purchaser, who in turn pays the seller in full. Some equity payment by the borrower is almost invariably required. The bulk of residential mortgage lending in the United States has been made on an installment, or amortized, basis since 1934. In addition, personal finance companies (also known as small loan companies or consumer finance companies), banks, and credit unions make loans to finance the purchase of consumer durable goods. In these instances, money is advanced to the purchaser-borrower and then repaid in periodic, usually equal installments. The purchaser-borrower has title to the goods. The seller receives his money in full. The lender is a creditor only, although in some states a chattel mortgage may be placed on the goods. If the chattel mortgage is employed, the lender can take action to possess and sell the goods in the event of default.

Installment sales credit, on the other hand, involves the extension of credit from the seller to the purchaser. The goods are advanced to

the purchaser after a fractional payment, called the down payment, is made and an installment sales contract is signed. This contract has three distinctive features: (1) title remains with the seller until full payment is made; (2) possession goes with the purchaser; (3) all payments and the goods revert to the seller in the event of default.

The installment sales contract originated with the idea that the goods in question were leased by the purchaser, with the installment payments treated as "rent" but credited against the purchase price. This made recovery of the goods relatively easy at law in the event of default. The legal fiction of a lease contract is still maintained in most jurisdictions. In Great Britain, in fact, the installment plan is still referred to as the hire-purchase plan.

The dealer or seller under an installment sales agreement must in turn obtain financing for his operations. For this purpose, specialized installment sales finance companies have developed. Their function is to provide funds for the sellers by buying the installment sales paper, or by advancing funds with the contracts as security. Such companies are either independent or subsidiaries of large selling concerns; the latter are strongest in the automobile and home appliance field. The subsidiary companies usually advance funds to dealers under what is known as the recourse plan. The dealer becomes liable to the company if loss is incurred as a result of default by the purchaser. Independent sales finance companies do not employ the recourse method.

Installment sales are best suited to the purchase of durable goods, as the benefits from such goods are derived over a prolonged period of time. As a consequence, their prices are relatively high. The prospective purchaser has the alternative of foregoing the enjoyment of the good while he saves the necessary purchase price out of income, or of borrowing the necessary funds and paying out of present income while he enjoys the good. Installment sales credit enhances the consumer's immediate purchasing power.

The use of installment credit in the United States originated in the furniture industry in the 19th century. The first use of installment credit in the sale of automobiles occurred in 1907. By 1910, automobiles accounted for the largest single segment of installment credit; the proportion has grown steadily since that time. After World War II, the enormous business of providing the funds for installment sales credit for automobiles in the United States was concentrated in three firms. The total outstanding automobile installment debt in mid-1957 was \$15 billion, up from less than \$1 billion in 1945 and \$6 billion in 1950.

The importance of installment sales credit, as opposed to installment loan credit, is indicated by the fact that after World War II over 80 per cent of total automobile installment debt was in the form of installment sales credit. The same was true of all other kinds of consumer goods, such as household appliances and furniture.

Not all installment credit is consumer debt, however. Business installment credit is occasionally advanced on durable goods at the wholesale level; but because the essential long-term aspect of asset enjoyment is missing, this is unusual. Also, railroad rolling stock is often financed on a quasi-lease basis via the equipment trust. Finally, real estate is occasionally financed by means of the land contract, which has all the characteristics of the installment sales contract

enumerated above. The only difference is that title may pass when something less than the full amount of the purchase price has been paid, say 60 to 75 per cent.

Total consumer installment credit outstanding in the United States was \$34.1 billion at the beginning of 1958. Of this total, installment sales credit was \$26.2 billion and installment loan credit was \$7.9 billion. See also BANKS AND FINANCE—21. *Installment Lending Institutions*.

Consult Cox, Reavis, *The Economics of Installment Buying* (New York 1948); Phelps, Clyde W., *Financing the Installment Purchases of the American Family*, Studies in Consumer Credit No. 3 (Baltimore 1955); Federal Reserve System Board of Governors, *Consumer Installment Credit*, 3 parts (Washington 1957).

WILLIAM N. KINNARD, JR.,
University of Connecticut.

INSTINCT, in'stingkt, often defined as a behavior pattern that is automatic, stereotyped, innate, inherited, predictable, and unlearned, as opposed to more modifiable learned behavior. Any absolute or even approximate distinction between the two types is, however, false, insofar as all behavior is at some specific point during individual development acquired as an activity of the organism's developing nervous and other associated systems. It may be instinctive for a man to swing his left arm forward as he takes a step with his right leg. He has, however, attained the capacity to coordinate these activities only after undergoing complicated development of his nervous, skeletal, muscular, and circulatory systems.

A question arises as to whether it might be wise to abandon the term "instinctive" as opposed to "learned" behavior, and rather to contrast *generic* behavior with *individual* behavior. Generic behavior would be that which is strictly and rigidly characteristic of the taxonomic category to which an organism belongs (for instance, the building of a specific type of nest by a swift, a hive by a swarm of bees, or the swinging forward of a man's left arm with his right leg); individual behavior would be that in which an organism can to a great extent improvise within the gamut of inherited behavior patterns (for instance, much apparently arbitrary human behavior). Even such a distinction is, however, sometimes blurred. A man can rotate his torso, turning to one side, in his adult life as a willed and individualized action, because he has heard an alarm, or seen a flower, or simply because he wishes to do so; this seems to be a learned and individualistic and acquired competence. Yet an identical movement is an obligatory part of the earliest observed spontaneous activity of every human fetus at about nine to nine and one-half weeks of age, and at this time it is an unlearned activity dependent on the maturation of specific inherited neural mechanisms.

If differences exist between learned and unlearned behavior, they must rest on differences within the organisms' nervous systems, and their analysis is thus to some degree a biological problem. It is, for instance, a biological fact that in organisms such as birds with highly rigid and ritualized behavior patterns evolved in connection with the practice of flight, behavior is governed by a different part of the forebrain than that which is dominant in regulating the more flexible behavior of mammals. Yet even within the realm of strictly biological analysis it remains difficult to correlate the existence of specific behavior

patterns with the structure of the nervous system alone. Symbolization and communication, once believed solely man's prerogatives and considered to have been evolved as a result of the elaboration of his particular kind of brain, are now accepted as accomplished in an entirely different fashion by bees, whose brains bear not the slightest resemblance to those of men in either number or arrangement of structural elements. See also ANIMAL PSYCHOLOGY.

JANE M. OPPENHEIMER,
Bryn Mawr College.

THEORIES OF INSTINCT

Instinct has traditionally been conceived as comprising complex patterns of behavior which are unlearned, involuntary directive forces in action, appearing in all members of a given species. Thomas Hobbes, in *Human Nature* (1650), differentiated between unlearned propensities in human behavior and those which an individual acquires as a result of experience. By implication, he taught that original human nature consists of instincts. William Paley, the English theologian, who wrote *Natural Theology* (1802), influenced many generations of university students in America and in England with the definition: "A propensity [later called an instinct] exists prior to experience (in the individual) and independent of instruction." These forces, he taught, have a divine origin and supply purposive direction for human behavior.

Alexander Bain (1818–1903), the Scottish psychologist, made the concept of instinct one of the central topics in his popular textbooks (*The Senses and the Intellect*, 1855; *The Emotions and the Will*, 1859). Impressed by Bain's clarity in dealing with this topic, William James adopted many of these concepts about instincts and their place in human behavior. His definition (*Principles of Psychology*, chap. 24) is familiar to all students of psychology: "Instinct is usually defined as the faculty of acting in such a way as to produce certain ends, without foresight of the ends, and without previous education in the performance."

Unlike Bain, James was greatly impressed by Charles R. Darwin's theory of evolution. An obvious kinship between man and lower animals is to be found in the instincts which they share in common. The higher up in the scale of evolution, the more instincts an animal possesses. Man, at the apex of evolution, has the largest number of all, and the most complex. Among those listed by James are the following: pugnacity, rivalry, fear, and acquisitiveness. The instinct of sociability among human beings has its counterpart in the gregarious behavior of many species of lower animals. Some instincts die out in early life, and others appear during later years of human life. Among human beings, James wrote, the instincts undergo many modifications imposed by the social group.

Sir John Lubbock (1834–1913) reported at length upon the manner in which instincts operate among insects, in his book *Ants, Bees, and Wasps* (1882). He believed that, directed by social instincts, these organisms achieve a remarkable order of community life. Many teachers of biology have believed that instincts among lower animals serve as purposeful guides to adaptive behavior. Thus, animals, which are not endowed with human intelligence, are able to survive individually and to maintain the species. The

anecdotal method, used by George John Romanes (1848-1894), furnished an abundance of illustrations about homing behavior, food hoarding, nest building, and the like. Conwy Lloyd Morgan (1852-1936) tried in vain to encourage his students to look for other explanations before invoking the concept of instincts to account for such activities among lower animals.

In 1919, Knight Dunlap (1875-1949) made an important address to the members of the American Psychological Association in which he vigorously criticized the concept of instincts. Much so-called instinctive behavior, he pointed out, is the result of learning. To be certain, if two small boys fight, one might say that they have an instinct of pugnacity; but, if asked to give evidence for that instinct, the instinctivist would have to say, "See! they fight!" Hence, the reasoning goes in a circle. Luther Lee Bernard (1881-), a sociologist at the University of Minnesota, proceeded to review all the literature dealing with instincts, animal and human, that had grown up since Bain. He reported (1924) that the concept is loosely defined, that no two writers ever agreed upon a list of basic instincts, and that much of the behavior called instinctive is the result of the learning process, not an innate endowment. As for lower organisms, Jacques Loeb (1859-1924) accounted for much of their behavior in terms of biochemical changes induced by stimuli. In America, therefore, it became "old fashioned" to make reference to instincts in animal and human psychology. The famous chapter in Bain's *Principles of Psychology*, if read at all, was regarded as a bit of quaint, though brilliant, metaphysical psychology.

In Europe, however, psychologists were not so ready to give up the concept of instinct. William McDougall (1871-1938), who went to America from England, made instinct (later referred to as propensity) a central topic in his system of psychology from 1908. Nikolaas Tinbergen (1907-) believes that it is impossible to account for the behavior of animals without making use of the concept of instinct. Current emphasis upon instinctual drives, popularized by the Freudians, has also given rise to the opinion that many American psychologists were too hasty in abandoning the concept. It should be noted, however, that contemporary animal psychologists who have reinvented the concept are inclined to give broad and ambiguous definitions for the term. Tinbergen, for example, who is thoroughly familiar with the research of contemporary European psychologists does not attempt to define instinct until he is halfway through his book. The Freudians, it should be noted, have a specialized definition for the term, and they are uninterested in the traditional discussions of James and others about instincts and their place in animal and human behavior.

PHILIP L. HARRIMAN.

INSTITUT DE FRANCE, ăN-stê-tû' dē frāns, official name for five learned societies in France: (1) Académie Française; (2) Académie des Inscriptions et Belles-Lettres; (3) Académie des Beaux-Arts; (4) Académie des Sciences; (5) Académie des Sciences Morales et Politiques. The institute had its origin in the old royal academies founded during the 17th and the 18th

centuries. These academies were suppressed during the French Revolution and the Institut de France took their place, being formally established by the Constitution of 1795, which reads in part: "There is for the Republic a National Institute, entrusted with the care of collecting records of all discoveries and furthering the progress of arts and sciences." The foundation's charter admitted only three sections: (1) Sciences Physiques et Mathématiques; (2) Sciences Morales et Politiques; (3) Littérature et Beaux-Arts.

The Institut de France was inaugurated in the Louvre on April 4, 1796. The ceremony was attended by the state ministers, the foreign ambassadors, and eminent Parisians. As Raymond Poincaré stated a century later: "Public homage was paid on that day to the unity of sciences by a rejuvenated nation." The scientists Lamarck, Georges Cuvier, Gaspard Monge, Pierre Samuel Dupont de Nemours, Claude Louis Berthollet, Jean Antoine Chaptal, Antoine Laurent de Jussieu, and the comte de Volney, as well as Napoleon Bonaparte, the sculptors Jean Houdon and Augustin Pajou, and the painter Jacques Louis David were among the first members of the new organization. Later Napoleon Bonaparte, when first consul, gave a special uniform to the members of the institute. When he became emperor he turned over to the institute the buildings of the old College of Nations, on the left bank of the Seine, opposite the Louvre. It took the name of Palace of the Institute. The name "Academy," suppressed by the Convention, was revived by Louis XVIII in 1816, after the downfall of Napoleon. Thenceforth the institute was composed of the five academies assembled. It has 231 members and 296 correspondents. Some of the correspondents are from various European nations, and some are Americans.

After the death of a member his seat is declared vacant. Candidates must give notice of their candidacy to the academy in which they wish to stand for election, which takes place some time later. There is a further delay between the election and the ceremonial reception when the new academicien is formally admitted.

During the 19th and 20th centuries the institute was enriched by many gifts, donations, and legacies which provide for the distribution of prizes and the printing of publications. In addition to its own library, which has 500,000 volumes, the institute administers also the Bibliothèque Mazarine, founded by Jules Cardinal Mazarin, and owns the Bibliothèque Thiers and the Bibliothèque Marmottan, each of which is housed in the mansion of its former owner. The institute inherited the collection of manuscripts, documents, and rare books assembled in the course of the present century by Charles de Spoelberch de Lovenjoul for the study of French literature of his time. The institute is also proprietor of: (1) the Château de Chantilly, with its grounds, woods, and farms, given by the duc d'Aumale, together with his art treasures and library, which were turned into a museum, the Musée Condé; (2) the Musée Jacquemart-André, in Paris, settled in a private mansion and showing tapestries, paintings, furniture; (3) the Abbey of Chaalis, near Senlis; (4) Langeais, a château on the Loire: given by the Siegfried family; (5) the Paul Marmottan museum, in Paris, located in the mansion of the donor; (6) the Villa Ile-de-France, near Nice, presented by Baroness Ephrussi, with its collections of antiques and works of

Eastern art, and turned into a museum; (7) the House of the Institute of France, in London, Foundation Edmond de Rothschild, for French students. This house was bombed by the Germans during World War II, the director and other inhabitants of the house being killed.

Numerous annual prizes are distributed by the institute to writers, scientists, and artists, and some prizes are used to reward the most virtuous actions and the books which may best further the progress of morality.

Académie Française.—This was founded by Cardinal de Richelieu, minister to Louis XIII, in 1635, when Richelieu asked a few poets and writers whether "they would not care to be formed into a company under the authority of the state, for the purpose of working at the development, unification, and purification of the French language." They were to do their best to make it as perfect a language as Greek and Latin used to be. When they had accepted the proposition, with various degrees of enthusiasm, their first task was to prepare a dictionary, the first edition of which appeared in 1694. Members of the academy have continued preparing revised editions of this dictionary to the present day. New editions were published in 1718, 1740, 1762, in the year VII (1798) of the Republic, in 1835, 1877, and in 1932-1935.

Pierre Corneille, Jean Baptiste Racine, Nicolas Boileau, Jean de La Bruyère, Charles Perrault, Jacques Bénigne Bossuet, Valentin Esprit Fléchier, Bernard Le Bovier de Fontenelle, and Jean de La Fontaine were among the first members of the academy. Molière never belonged to it. On the other hand, many aristocrats, who had very little to do with erudition, found their way into this institution, which always enjoyed royal favor. During the 18th century Voltaire, Jean Le Rond d'Alembert, the marquis de Condorcet, and many of the other Encyclopedists were academicians. All the foreign monarchs and princes and the most illustrious visitors to Paris used to attend meetings at the academy. Following this tradition, Gen. John J. Pershing was solemnly received there during World War I. During the first part of the 19th century, when the romantic school of writers was at its height, the academy stood for tradition, and it took a long time for members of the new generation to be elected. Alphonse de Lamartine and Victor Hugo succeeded only after a long wait and many rebuffs.

Among the prizes distributed by the academy, the most important are: (1) *Prix de la langue française*; (2) *Grand prix de littérature*; (3) *Prix du roman*. Other prizes reward authors of books intended to improve morals, books on French history, the best new comedy played at the Comédie Française, and the best translation of a foreign book into French. Other prizes go to people who have led an exceptional, virtuous, and productive life and to people who have reached a high level of family, social, or moral perfection.

Membership in the Académie Française is limited to 40 at any given time. The following is a list of the members in 1965, with year of election given in parentheses after each name:

Marcel Achard (1956)
Louis Armand (1963)
Marc Boegner (1962)
Marcel Brion (1964)
Duc Louis de Broglie (1944)
Jérôme Carcopino (1945)
André Chamson (1956)

Jacques Chastenot (1956)
René Clair (1960)
Jean Delay (1959)
Georges Duhamel (1935)
André François-Poncet (1952)
Maurice Garçon (1946)
Pierre Gaxotte (1953)

Maurice Genevoix (1946)
Étienne Gilson (1946)
Jean Guéhenno (1962)
Jean Guiton (1961)
Comte Robert d'Harcourt (1946)
René Huyghe (1960)
Marshal Alphonse Juin (1952)
Joseph Kessel (1962)
Jacques de Lacretelle (1936)
Duc de Levis-Mirepoix (1953)
Henri Massis (1960)
Thierry Maulnier (1964)

François Mauriac (1933)
André Maurois (1938)
Henry de Montherlant (1960)
Comte Wladimir d'Ormesson (1956)
Marcel Pagnol (1946)
Jean Paulhan (1963)
Jules Romains (1946)
Jean Rostand (1959)
Jacques Rueff (1965)
Cardinal Tisserant (1961)
Henri Troyat (1959)
Pasteur Vallery-Radot (1944)

At the time this table was compiled, there were two vacancies in the Academy membership for which successors had not been elected.

Académie des Inscriptions et Belles-Lettres.—This was created by Jean Baptiste Colbert in 1663 and was first called "The Little Academy," then "Academy of Medals," then "Royal Academy of Inscriptions and Medals" in 1701. Its present name dates from 1716. Suppressed by the revolution, it revived when the institute was created. The Académie des Inscriptions et Belles-Lettres is mainly interested in historical studies and investigations concerning numismatics, ancient documents, and inscriptions in living and dead languages. It awards numerous prizes for historical research every year. With its 55 members are 12 foreign associates and 70 correspondents, 30 French and 40 of other nationalities. Correspondents from the United States include Lynn Thorndike, William F. Albright, Albrecht Goetze, and Elias A. Lowe.

Académie des Beaux-Arts.—This was created in 1648 by Charles Le Brun, appointed first painter to the king by Louis XIV. The name of this academy was then "Royal Academy of Painting and Sculpture." Its present name dates from 1795. For many years the academicians held their meetings in the Louvre. There are 41 members who are divided into five sections: painting, sculpture, architecture, engraving, and musical composition. A school governed by the Académie des Beaux-Arts was founded in Rome in 1666 to help French artists in their studies of antique and Italian arts. It is located in the Villa Medici. The academy also administers the École des Beaux-Arts in Paris. Before the French Revolution it was the only academy to admit women to membership. One of the last women elected was Marie Vigée-Lebrun. Its first American associate was Benjamin West. John D. Rockefeller, Jr., became one of the 10 foreign associates. Among the 50 correspondents of the Académie des Beaux-Arts are the Americans Paul Manship, for sculpture, and Welles Bosworth, for architecture.

Académie des Sciences.—Created by Colbert in 1666, this academy has 76 members, 12 non-residents, 6 members for the application of science to industry, 20 foreign associates, and 120 correspondents, divided into two groups: (a) mathematics and physics, (b) chemistry and natural history. These two groups are divided into 11 sections: geometry, mechanics, astronomy, geography and navigation, physics, chemistry, geology, botany, zoology, rural economy, and medicine and surgery. Benjamin Franklin was a foreign associate of this academy, as was Albert Einstein. The Académie des Sciences started distributing prizes as early as 1721, and since that time the number of prizes awarded has steadily increased. One of the latest prizes was

founded by Prince Albert I of Monaco.

Académie des Sciences Morales et Politiques.—Founded in 1795 and named "Classe des Sciences Morales et Politiques," it was suppressed in 1803 by Napoleon, who appreciated neither its inquisitive spirit nor the comments and criticisms of the academicians on political matters and social controversies. It was restored with its present name in 1832 and joined the four other academies. It is divided into five sections: (1) philosophy; (2) morals and sociology; (3) legislation, public law, and jurisprudence; (4) political economy, statistics, and finance; (5) history and geography. In addition to 40 academicians there are 60 correspondents, 10 free members, and 12 foreign associates including President Dwight D. Eisenhower, elected to General Pershing's seat.

YVON BIZARDEL,
Honorary Director of Fine Arts, Museums, and
Libraries of the City of Paris.

INSTITUTE FOR ADVANCED STUDY, The, in'stī-tūt, located at Princeton, N.J. Originally conceived as a graduate school with a faculty which would have no undergraduate obligations, the institute has actually been from its start a research center for eminent scholars doing advanced work in their fields of specialization. Although it relies heavily upon the facilities of Princeton University, it is a completely separate organization. No degrees are awarded, as all members are required to have the highest degrees in their respective fields in order to qualify for the institute. In 1956 there were two schools at the institute, one for mathematics and one for historical studies. There were about 40 long-term members, of whom approximately half were members of the faculty. In addition there were about 100 temporary members in residence for short terms of one or two years. Admitted by faculty vote, many of these members are invited to the institute in the belief that their participation will be of mutual benefit to them and to the long-term members. Applications for admission are also accepted.

The Institute for Advanced Study was founded in 1930 by Louis Bamberger and his sister, Mrs. Felix Fuld, with a donation of \$5 million, and it opened in 1933 under the directorship of Abraham Flexner. Flexner was succeeded as director in 1939 by Frank Aydelotte, and Robert Oppenheimer became director in 1947.

INSTITUTE OF INTERNATIONAL EDUCATION, established in 1919 by Nicholas Murray Butler, Elihu Root, and Stephen Duggan "to enable our people to secure a better understanding of foreign nations, and to enable foreign nations to obtain accurate knowledge of the United States, its people, institutions and culture." It is a private, nonprofit agency which acts as a clearinghouse for information on all phases of international education and administers exchange-of-persons programs—including the Fulbright program for graduate students—for government agencies, foundations, organizations, col-

leges and universities, and corporations in the United States and abroad. Each year over 4,500 students, teachers, technicians, and specialists study or train in a country other than their own through institute programs. Through its New York City headquarters and its regional offices in Chicago, Denver, Houston, San Francisco, and Washington, D.C., the institute works to bring foreign students and visitors into closer contact with the American community. With the cooperation of regional committees these offices arrange home hospitality, field trips, and recreation programs for visitors from abroad.

As a public service the institute's Department of Information answers requests for information and counseling on all phases of international education: scholarship opportunities, fields of study in the United States and abroad, opportunities for teachers and specialists. It issues publications, maintains a library with catalogues of most institutions of higher learning in the United States and abroad, and provides information concerning other organizations in the field of international education. The institute has also developed the Central Index of Educational Exchangees, a roster of more than 250,000 persons who have studied, taught, or trained in countries other than their own since 1919.

The institute seeks to provide coordination in the field of international education by sponsoring conferences and meetings bringing together interested individuals from education, government, business, labor, the arts, and religious and civic groups. It offers program guidance in the form of information on current activities in specific fields or geographic areas, and gives counsel based on experience with specific operations, such as the selection of candidates, fiscal management, or the placement of foreign students, to organizations, institutions, and corporations interested in establishing new programs.

INSTITUTES OF ORATORY, a treatise by Quintilian (Marcus Fabius Quintilianus), the famous Roman rhetorician (35?–100 A.D.). *Institutes of Oratory* is the traditional English title, but more correctly it should be *Oratorical Education* (Latin, *Institutio oratoria*). Quintilian published it in 12 books (c. 95 A.D.) after some 20 years' rich experience of successful instruction in oratory at Rome. Though much of the treatise is highly technical, it still has great interest as a lasting monument of Roman genius in treating practically a subject whereon Greek genius abstractly theorized.

Book i discusses an orator's training and contains penetrating observations on pedagogy; its later chapters on language are important to students of Latin. Book ii treats of the several rhetorical schools, the declamations (which played a prominent part in instruction), and the nature and value of oratory. Books iii–ix are rather technical, devoted to kinds of oratory, types of causes, formal structure of a speech, proofs, syllogistic arguments, emotional appeal, style, propriety of words, ornament, figures of thought and of speech, artistry, and rhythm. Book x reviews Greek and Latin literatures from the rhetorical viewpoint and is of prime worth for critics of classical literature. Book xi explains memory and mnemonics and discusses delivery, gesture, and attire. Book xii treats higher themes: importance of character, educative value of philosophy and of law, oratorical ideals, appropriate use of dif-

ferent oratorical styles, and advantages derived from successful training as an orator.

The best Latin edition with English translation is by Harold E. Butler, *The Institutio Oratoria of Quintilian*, 4 vols. (London 1921-22).

P. R. COLEMAN-NORTON,
Princeton University.

INSTITUTES OF THE CHRISTIAN RELIGION, *The (Christianae Religionis Institutio)*, treatise by John Calvin (q.v.) published in the original Latin at Basel, 1536. His first French version (1541) is a landmark of French prose. Intending it as a short clarification of Protestant doctrine for believers, Calvin kept revising and enlarging; the original six chapters eventually grew to four books (Lat. ed. 1559; Fr. ed. 1560).

INSTITUTIONS, *Social*, in-stī-tū'shūnz, one of the fundamental categories of modern sociological science. Full agreement on the definition does not, however, exist among specialists. One conception is that an institution should be defined as a *complex of norms* regulating the actions of persons in the process of social interaction. A typical example is the institution of property, regulating behavior where the acquisition, use, control, and disposal of objects of possession are concerned. Though the objects may be physical, property essentially defines the rights and obligations of people in relation to each other where such objects are involved. Another typical example is authority, which is a complex of norms regulating behavior conceived to be necessary to the attainment of the common goals pursued in a collectivity. A central aspect of authority is the right to impose and obligation to accept binding decisions, the enforcement of which may involve coercive sanctions.

The principal alternative to the above definition is the concept which identifies an institution with a group or collectivity; thus a university or a hospital or even the military establishments may be referred to as an institution. In such usage the term is likely to be reserved for relatively large and formalized collectivities, sometimes referred to as *formal organizations*.

For many purposes close to the level of common sense the difference between the two is not vital, but for more refined analytical purposes it becomes important because the same institutions characterize many different collectivities which differ from each other in other respects. Thus the same institution of property applies to business corporations, private nonprofit organizations, and even in some respects to government agencies. The same institution of contract obtains, for example in the field of employment, within considerable limits, whatever the character of the organization. At the more formalized level in modern societies, the law is the focus of the definition of institutions.

An institution, it has been indicated, regulates action. Detailed prescription is only one aspect of that regulation. In general, besides prescriptions, an institutional complex will incorporate prohibitions—that is, it will define the limits of acceptable behavior; and between these two there will be a range of permitted behavior which is neither prescribed nor prohibited. Within the permitted range negative sanctions or punishments will not be applied, but there may be differential rewards for different levels of approved performance.

Thus where the obligation to complete a secondary education may be said to be institutionalized, as it is for certain population groups, "passing" work may be satisfactory, but special rewards will be given for excellence; "failure," however, will be definitely punished, at the least by disapproval. Different institutions vary greatly, both in the same society and from one society to another, in the relative emphases on these three components of the definition of rights and obligations.

Institutions are aspects of the structure of social systems. A cognate concept of process, *institutionalization*, is also common. This refers to the process by which a norm or a pattern of behavior has come to be expected of those occupying given statuses in a society—the extent to which the type of behavior in question comes to be "done," in the normative sense, in the society. So far as this is the case, the tendency will be (1) for behavior in conformity with the norm to be rewarded by others with whom the individual interacts, and for deviation from the norm to be punished; and (2) for the institutional "role-expectation" to become internalized—the individual, as part of his psychological structure, will want to do what he is expected to do. Thus in a society which values achievement in occupational roles, "ambition to succeed" is the internalized counterpart of the institutionalized expectation of high occupational performance. In this sense institutionalization is a matter of degree; for example, both external sanctions on achievement and internalized commitment to it vary greatly in different population groups.

Institutions in the present sense constitute the most important category for the analysis of variations in structure as between different societies and, correspondingly, in the structure of the same society at different times. Thus the modern institution of ownership as a form of property is very different from the medieval patterns of tenure. Bureaucratic authority in the modern business firm is very different from the purportedly divine authority of the Hebrew prophets or the authority of such political leaders as Adolf Hitler. The technical classification of institutional patterns is the main framework for the analysis of social variability.

TALCOTT PARSONS,
Professor of Sociology, Harvard University.

INSTRUMENT OF GOVERNMENT, in'strōō-mēnt, the first written constitution in English history. Under it Oliver Cromwell governed England, Scotland, and Ireland from Dec. 16, 1653, to May 1657. It consisted of 42 articles and vested the legislative power in the hands of "one person and the people assembled in parliament." The executive power was placed in the hands of Cromwell as lord protector of the Commonwealth; his office was made elective, and he was to be assisted as executive by a council of state of 21 members, appointed for life. The Parliament was to consist of a single chamber. A new Parliament was to be called every third year, and a Parliament could not be dissolved in less than five months except with its own consent. There were 460 members—400 for England and Wales and 30 each for Ireland and Scotland. The distribution of borough seats was improved, and the property qualification for voters in the counties was changed from the 40 shilling freehold to ownership of land or personal property of the value of £200.

Roman Catholics and those who had opposed Parliament during the Rebellion were disfranchised. This constitution contained several elements of weakness and its downfall was assured as soon as it dared assert its independence of or opposed the lord protector.

Consult Gardiner, Samuel Rawson, *Constitutional Documents* (Oxford 1889); and Jenks, Edward, *Constitutional Experiments* (London 1891).

INSTRUMENTAL MUSIC. See MUSIC; MUSICAL INSTRUMENTS; ORCHESTRA MUSIC.

INSTRUMENTALISM, in philosophy, a system, akin to pragmatism, according to which thought is considered an organic function, the object of which is to maintain the even tenor of experience, restoring the latter when it is interrupted or confronted by a special situation. See EPISTEMOLOGY; PRAGMATISM.

INSTRUMENTATION, in music, the arranging of music for a combined number of instruments. The nature and character of the musical ideas must determine whether the instrumentation shall be simple or artistic, and perhaps complex; the latter being the case when some of the instruments take a more prominent part than others. For both purposes, a thorough knowledge of every instrument in the orchestra is absolutely necessary, as without this instrumentation becomes only a deafening mass of sounds. The stringed instruments, from their nature, in most cases, form the principal parts of a score, around which the other instruments move, without depriving them of their importance. The wind instruments represent, more or less, a subordinate chorus, which may again be divided into two kinds: the wood instrument and the brass, which, with the stringed instruments, give three essentially different choral effects, that may be mixed together in endless variety. A knowledge of the art of instrumentation is acquired only by great experience; at the same time much may be learned by consulting the best works on the subject such as Berlioz, Louis Hector, *Traité d'Instrumentation*; Gassner, Ferdinand Simon, *Partiturerkenntnis*."

INSTRUMENTATION. The drive for mass production in industry initiated by World War II stimulated the drive for the development and use of instrumental methods of chemical analysis. The trend has been along three distinct lines: (1) Application of recent electronic developments toward the manufacture of commercial instruments to measure well-known physical properties with a precision and rapidity hitherto unattainable; (2) the automatizing of single- and multiple-unit operations either to record automatically specific physical characteristics or both to record and control as in the case of temperature regulation or by actuating valves for introduction of reactants; (3) the development of new techniques, notably ultramicroscopic and radioactive tracer methods.

Most notable developments have been in the spectrophotometric field, both in emission and absorption spectroscopy, and cover almost the entire range of measurable electromagnetic radiations. Although well-known since the time of Robert Wilhelm Bunsen, the science of emission spectroscopy has not been extensively applied to routine industrial control problems until the last decade. During this time the spectrograph has

developed from a relatively simple light-resolving instrument, useful for qualitative work but of relatively minor importance for quantitative estimations, to a complex electronic device which permits the rapid (one to two minutes) precise estimation of multiple constituents. This has been particularly useful in the metallurgical field for the rapid testing of minor constituents in aluminum, magnesium, steel, and other alloys. A typical example is the Quantometer, a grating-type instrument, which not only resolves the spectrum excited by an aluminum spark, but which simultaneously measures the relative intensities of specific lines for as many as sixteen elements which are usually present in relatively small amounts. By previous calibration, the intensities of the specific lines actuate counters so that the actual percentage of each of the elements may be directly read from the instrument as soon as the spark discharge (30 to 120 seconds) stops. Thus, the analytical control work for a melt of aluminum which used to require days of painstaking wet chemical analyses is accomplished in a matter of minutes. Such a development could not have been accomplished except for the development of highly sensitive and stable electrical components. These are essential for a consistent power supply, as well as for the measurement of the low level light intensities involved.

By the use of quartz optics and photocells sensitive to low levels of ultraviolet radiations, highly precise and rapid quantitative absorption work is now possible in the ultraviolet region of the spectrum (notably from 2100 to 3500 Å). The Beckman DU model spectrophotometer has given great impetus to this field by making generally available an instrument which is stable and relatively easy to operate and which permits either absorbancy or per cent transmission measurements at highly monochromatic wavelengths with great rapidity and with a precision of one per cent. Thus, it is now possible to use ultraviolet absorption bands of substances not only for identification purposes, but also for highly precise quantitative measurements. This technique has been of particular value in the field of organic chemicals, notably in the fields of pharmaceuticals and dyestuffs.

A recently marketed double-cell instrument which uses photomultipliers and which automatically scans the entire ultra-violet (U.V.) region, comparing a sample in solution against a solvent blank, now enables the chemist to chart accurately the U.V. spectrum of a compound in a matter of two to ten minutes depending upon the detail desired. In such an instrument the slit width is automatically controlled simultaneously with the wavelength drive so as to obtain maximum resolution and optimum sensitivity at each wave length. For such instruments, hydrogen discharge lamps serve as continuous energy sources.

In the visible region of the spectrum many precise and direct reading photoelectric spectrophotometers are available including filter type, replica grating, and glass prism-type instruments. The filter type are the simplest in construction; because of their ruggedness and relatively low cost, they are used most widely for routine control work. These instruments have largely replaced the visual-type colorimeters which were so very dependent upon the individual operator's eyesight and personality.

The availability of commercial instruments applicable to the infrared region of the spectrum now permits this region to be used widely. Relatively simple single-purpose instruments are in common use for controlling gas streams or for measuring the change in concentration of a single component. For general survey work over large portions of this region of the spectrum, instruments with sodium chloride prisms, lenses, and cell windows are being widely used in the 1.5 to 15.0 micron region. Other optics, such as potassium bromide and silver iodide, have extended the useful region up to 25.0 microns. These instruments are now widely used for the characterization of compounds—the infrared spectrum of each substance being sufficiently complex so as to be likened to a "fingerprint" of the substance. The ability specifically to identify definite groups within the molecule, namely nitrate groups, sulphate groups, and others such as $C-O-C$, $C=C$, $C=O$, free $O-H$, $N-H$, is making this technique of particular value to synthetic organic chemists. In the petroleum field, distillate composition is being rapidly controlled by absorbency measurements at different wavelengths, each more or less specific for a definite component, followed by calculations involving the solving of simultaneous equations so as to yield quantitative data for each constituent. The simultaneous determination of four component systems is commonplace, and as many as eleven and twelve component systems may be resolved in this fashion. This development has been made possible by the availability of electronic computers since the manual solution of simultaneous equations involving four, five, six, and more unknowns would be economically impossible because of the man-hours of calculations required.

For routine survey use in the infrared region, both single- and double-beam instruments are commercially available. Either Nernst glowers or globar elements are used for energy sources with bolometers or thermocouples being used as pickups. Since direct currents of very low energy levels are involved, suitable precise measurement has been a problem. A common practice in use is to employ a beam chopper in the light path so as to convert the direct current to a pulsating current which may then be handled like alternating current for amplification. A recent innovation permits direct transmission readings in a single-beam instrument. In this instrument a solvent blank is initially scanned, the slit width being automatically adjusted to give 100 per cent transmission over the region being investigated. The necessary slit-width settings are automatically recorded on a wire recorder, and when a sample is then placed in the path, the wire recorder continuously adjusts the slit width so that it becomes possible to obtain a differential absorbency curve (of sample versus solvent). Some of the advantages of such a system include measurement of the sample in the same cell as the blank and the lack of necessity of having two perfectly balanced beams. Such an instrument is, of course, dependent upon its electrical stability between runs and its sensitivity to line voltage fluctuations.

The development of sensitive flame photometers permits rapid determinations of potassium, sodium, lithium, and other elements by atomizing the sample into a hot gas flame and measurement of the intensity of specific lines energized therein. Sensitivities down to 0.1 parts per million by this technique are now commonplace.

The two major war products, radar and atomic energy, have introduced radical changes in the laboratory. The atomic energy project, of course, is now making available to the chemist radioactive elements which were never available before and which can be used for "tracer" techniques. A whole new field of instrumentation has been introduced for these "tracer" studies by the construction of rapid and sensitive Geiger-Müller counters, scaling, and recording units.

In fields other than the photometric, progress has been also outstanding. The really first new developments in the construction of an analytical balance in 50 years have resulted in a direct reading balance which operates under constant load, and thus constant sensitivity, and enables direct weighing of substances with a sensitivity of $\frac{1}{20}$ of a milligram (total load 200 grams).

The glass electrode is now universally used both for the measurement of pH and for the automatic control of acidity. New glasses have permitted the manufacture of sturdy, heavy-walled and sensitive electrodes applicable over a wide temperature range and useful at high pH values.

Automatic titration assemblies are now readily available which carry out either electromotive force type titrations (acid-base, oxidation-reduction, and precipitation type reactants) or polarization type ("dead stop") titrations automatically. In these instruments a measured sample is added to a suitable titration vessel, the instrument is set for the desired endpoint, and the titrant is then automatically added until this endpoint is reached.

The use of the polarographic technique is being advanced along two lines. Recording instruments (either pen and ink or photographic) are now available which automatically trace a polarographic curve, using the dropping mercury electrode, over any desired voltage range. On the other hand, the rotating platinum electrode is being used for amperometric titrations at fixed voltages. With the advent of standardized diffusion current constants, it is necessary that the rate of flow of mercury, m , from the dropping mercury electrode be known precisely. For this purpose an automatic mercury-measurer is now available.

High-frequency induction-type furnaces have been introduced, primarily for the determination of carbon and sulphur in steels. In these furnaces the power consumption is relatively low since it is only in use during the actual combustion of the sample. High-frequency oscillator circuits have also been introduced to carry out electrodeless titrations. Primary applications have been to halogen titrations.

The mass spectrograph is being commercially utilized primarily for the analysis of multicomponent hydrocarbon mixtures although its original use for the separation and measurement of mass isotopes continues.

The field of extraction is now playing a very important part in the separation of closely related rather complex substances. This has made itself felt by a host of workers in the field of counter-current distribution studies wherein a solute is permitted to come to equilibrium between two immiscible solvents. As a result, rather complex mechanisms have been devised to permit continuous stage countercurrent distribution studies by automatic robots.

In the field of gas analysis many specific physical measurements are being utilized for au-

tomatic control. A magneto-acoustical system is in commercial use for the detection of a few hundredths of a per cent of oxygen. Interferometric methods are in use for the analysis of nitrogen-argon mixtures. Manometric methods for many gases permit automatic recording of the pressure involved. A very sensitive differential manometer which can detect differences as low as 0.000001 atmosphere over a range of 1 mm. of mercury to 1 atmosphere depends on the principle of the aneroid barometer. The measurement depends upon the motion between a pair of nesting diaphragms which are soldered together to form a very thin capsule containing the gas or vapor. One diaphragm remains stationary and the second is attached to a displacement gage with the four resistance wires serving as a Wheatstone bridge.

Viscosity measurements of liquids are now largely based on measurement of the torque exerted on a rotating stirrer. A wide range of viscosities may be measured by using different sized or shaped spindles, paddles, or disks, together with various strength torque springs. This procedure lends itself to automatic recording.

Electrical titration methods are generally limited in their use by the nature and sensitivity of the electrodes used. Recently, the introduction of high-frequency oscillator titration circuits has permitted titrations without any electrodes being immersed in the titration cell. Three factors govern the characteristics of an oscillator which includes a liquid or solution in its tank circuit. These factors include the circuit constants of the oscillator, the volume of the solution and its location in the circuit, and the conductance of the solution as affected by its ionic or dipole concentration. The changes in conductance during a titration cause variation in such loading and thereby permit the course of a titration to be precisely followed without electrodes being actually immersed within the solution. This new method of analysis thus utilizes the energy absorption from a high frequency field as the basis of a new conductometric method of analysis. Wide use of this technique is being made in the determination of chlorides in water, especially as related to the petroleum field. It will undoubtedly be applied to other fields and other types of titrations as chemists become familiar with the principles.

INSUBRES, a Celtic people of northern Italy. In the 4th century B.C. they settled in the region between the Alps and the Apennines. They were frequently at war with the Romans after 222 B.C., and in 194 their capital Mediolanum (Milan) was taken and they were finally brought under the yoke of Rome.

INSULAR CASES, a series of legislative problems created by the "accretion" to the United States of insular possessions following the Spanish American War in 1898. They arose over

Pres. William McKinley's recommendation in his message on the convening of the 56th Congress, Dec. 3, 1899, that "legislation should be enacted establishing a civil government in Puerto Rico," and involved the status of the citizens of our insular possessions and the constitutionality of an intra-national revenue tax. The Foraker Act, April 11, 1900, defined the relation of the island to the United States, by placing it on a status outside of the Constitution and also outlined a scheme for the government of dependencies that obligated the nation to a new and united policy. This gave rise to the Insular Cases which debated the question of the right to demand duty for commercial articles imported into the United States from Puerto Rico. On appeal the Supreme Court decided that the insular possessions were obtained under the clause regulating the making of treaties, and "that the power to acquire territory by treaty implies not only the power to govern such territory, but to prescribe upon what terms the United States will receive its inhabitants, and what their status shall be."

INSULATION. From the generation of electricity to the use of electricity, the two fundamental materials required (not including magnetic materials) are conductors and insulators, the one being as important as the other. Electrically speaking, all material may be divided into two general classes, conductors and insulators, depending upon their relative resistance to the flow of electricity. Conducting materials must have low resistance; and insulating materials, high resistance. Insulating material is required where mechanical contact is made by the conducting material. From an economic standpoint, conducting material is limited to copper and aluminum, but for insulating purposes many materials are available.

Insulation resistance is the resistance of the material to the passage of current. It is proportional to the thickness of the material (if the material is homogeneous), and inversely proportional to the area. Insulation resistance is measured in ohms, or in megohms (1 megohm = 1,000,000 ohms).

Dielectric strength is the strength against breakdown under electric stress. It is usually expressed in terms of the voltage per unit thickness (usually volts per mil) at which the insulation fails or becomes punctured. It does not vary with area, but increases when the thickness increases.

The output rating of a piece of electrical equipment is limited by the temperature its insulation can withstand without excessive deterioration. Common types of organic insulation, such as cotton, silk, linen, and paper, rarely permit a rated temperature rise greater than 55°C. (131°F.) over an ambient temperature of 40°C. (104°F.). Where higher temperatures are unavoidable, asbestos can be used if the attendant space factor is not prohibitive, and if the low tensile and dielectric strengths are not of great importance. Mica had been employed extensively, but its lack of mechanical strength and its high cost have imposed certain limitations on its use. The maximum operating temperature of electrical apparatus is now limited only by the qualities of the impregnant used.

Electrical Insulating Material.—The selection of insulating material depends upon several

factors, such as low power factor, high dielectric and mechanical strength, flexibility, and resistance to heat, abrasion, moisture, and deterioration. Porcelain is a good insulator which possesses practically all the foregoing characteristics except flexibility. Rubber, on the other hand, is flexible but will not stand heat or abrasion. The most widely used insulating products are combinations of several materials, such as mica, paper, and varnish. Paper, for example furnishes the base upon which mica is fastened by means of varnish; the combination possesses good dielectric strength, flexibility, and resistance to moisture.

CLASSIFICATION OF INSULATING MATERIALS

Thermal Classification.—Insulating materials are divided in this category into four classes: Class O, Class A, Class B, and Class C, which are thus defined by American Institute of Electrical Engineers standards.

Class O.—This insulation consists of cotton, silk, paper, and similar organic materials not impregnated with, nor immersed in, oil. The temperature limitation is 85° C. (185° F.).

Class A.—This group includes cotton, silk, paper, and similar organic materials impregnated with, or immersed in, oil; also enamel as applied to conductors. The temperature limitation is 125° C. (270° F.).

Class B.—This category includes inorganic materials, such as mica and asbestos, in built-up form combined with binding substances. If Class A material is used in small quantities in combination, for structural purposes only, the combined material may be considered as Class B, provided that the electrical and mechanical properties of the insulated winding are not impaired by the application of the temperature permitted for Class B material. Temperature limitation is 145° C. (293° F.).

Class C.—This insulation consists of inorganic materials, such as pure mica, porcelain, slate, glass, and quartz. There are as yet no stated temperature limits for these materials.

Physical Classification.—Insulation materials are physically classified as solids, liquids, plastics, varnishes and lacquers, and gases.

Solids.—In the group of solids there are: *natural solids* such as marble, slate, asbestos, quartz, mica, lava, soapstone, Alsifilm (ben-tonite); *vitreous solids* such as, glass, porcelain, and Mycalex (inorganic thermoplastic); the *fibrous* (treated and untreated) organic solids, including asbestos, cellophane, cotton, glass yarn, hemp, linen, nylon, paper, rayon, silk, and wood; and the *lastics*, which include buna, gutta-percha, koroisel, natural rubber, neoprene, thiokol, and ethylene polysulphide.

Liquids.—Among liquids used as insulation are *natural oils*, such as linseed, tung, pine, and castor, which are used in insulating varnishes, or in binders for built-up insulation; *mineral oil* (transformer and switch); *varnishes*; *synthetic liquids* (chlorinated derivatives of the benzenoid hydrocarbons) such as Pyranol, Inerteen and Dykanol "A," all of which are fireproof. Solvents are not used as insulation directly, but insulating varnishes and compounds include amyl and butyl acetates, acetone, alcohols, benzene, benzine, carbon tetrachloride, naphtha, petroleum, toluene, and turpentine.

Plastic Materials.—Several types of plastic materials are used for electrical insulation. The

gums or natural plastics include asphaltic, coumarone-indene, fossil, shellac, and vegetable (applied as liquids, melted, dissolved, or in liquid suspension). *Cold-molded plastics* include portland cement and filler, calcium silicate and filler—both impregnated with resins or asphalts; *waxes* used are beeswax, mineral, and paraffin. Two types of *synthetic resins* are used for insulation—the molded and laminated plastics, such as acrylic, alkyd, casein, melec, phenolic, resorcinol, formaldehyde, rubber, urea, formaldehyde and urea furfural, vinyl copolymers; and the cellulose compounds (therma plastics), such as cellulose acetate, cellulose acetobutyrate, ethyl, cellulose, and nitrocellulose.

Varnishes and Lacquers.—Insulating materials of this type are manufactured from natural gums and oils, and from synthetic resins. There are also hybrids; spirit varnishes, wire enamel, and solvent varnishes.

Gases.—Among insulating gases used in electrical insulation are air, carbon dioxide (CO₂), nitrogen (N₂), hydrogen (H₂), and rare gases such as helium, xenon, argon and krypton.

The properties and general characteristics of some of the insulating materials mentioned above are given in Table 1.

MATERIALS AND THEIR USES

A brief description of some of the best known insulating materials and of the way in which they are used is given in the following paragraphs.

Glass.—One of the oldest substances used for insulating purposes is glass. While the principal application of glass insulation has been for rigid insulators, recent developments have made it available in fabricated, flexible form.

Porcelain.—Like glass, porcelain is an excellent rigid insulator, but is not available in flexible form. Its principal use is for buildings, high voltage insulators, cleats, and bodies of wiring devices. Porcelain possesses high dielectric and fair mechanical strength, and is resistant to heat, moisture, and deterioration, but its lack of flexibility greatly restricts its use. Next to glass and cotton, it is the oldest of all insulating materials.

Slate.—This material is especially suitable for use wherever rigid insulating support is required for mounting switches and for control equipment. Slate, obtainable without metallic veins, has high insulation resistance and sufficient dielectric strength for all medium-voltage service, it cannot carbonize; thus in case of "flashovers," or electrical breakdown, it prevents short-circuiting. Slate is also resistant to heat, moisture, chemical fumes, and oils. In the early days of the industry, slate was used for switchboard panels. While it is still used for this purpose in limited quantities, substitutes are taking its place.

Marble.—This decorative material was once used for switchboards, especially in locations exposed to the public view. Its insulating characteristics are about the same as those of slate.

Mica.—Widely used as insulation is mica, an anhydrous silicate of aluminum and potash, or sodium, mined in the form of large laminated crystals. It is readily split into thin, tough, parallel-sided laminae, or flakes, with thicknesses as thin as 0.0008 mm. It has high insulation qualities and will withstand high temperatures. In its natural state, mica is impure, lacks flexibility, and has excessive surface leakage. Therefore the laminae are separated according to purity, and

TABLE 1—PROPERTIES OF INSULATING MATERIALS

Material	NEMA Temp. Class	Description	General Application	Usual Thickness	Dielect. Breakdown Volts per Mil
Cotton Tape	O, A		Coil finishing	0.005 to 0.015	20
Asbestos Tape	B		Coil finishing	0.007 to 0.015	20 to 70
Glass Tape	B		Coil finishing	0.003 to 0.015	96
Mica Tape	B	Built-up mica on paper or cloth	Armature coil winding	0.005 to 0.010	600 to 700
Kraft Paper	O, A	Tough brown paper	Layer insulation and wrappers	0.003 to 0.005	60 to 150
Glassine Paper	O, A	Glossy-hard translucent	Layer insulation	0.001 to 0.002	200
Varnished Paper	A	Varnish-treated paper	Layer insulation	0.002 to 0.005	900
Fish Paper	O, A	Extra-tough heavy paper	Pads, outer layer insulation	0.004 to 0.015	200
Asbestos Paper	B	Paper made of asbestos fibers	Layer insulation	0.010 to 0.025	20 to 200
Fish Paper and Mica	B	"Sandwich" of two materials	Wrapper insulation	0.010 to 0.020	400
Varnished Cambric	A	Varnish-treated cloth	Layer insulation and wrappers	0.007 to 0.010	1000
Varnished Silk	A	Flexible varnish-treated silk	Layer insulation and wrappers	0.002 to 0.004	1000
Flexible Mica	B	Built-up mica with flexible resinous binder	Terminal insulation and wrappers	0.010 to 0.060	500 to 600
Vulcanized Fiber	O, A	Chemically converted paper. Sheets and tubes.	Motor insulation and arcing resistance	0.005 to 2.000	50 to 350 ¹
Phenolic Laminated Plastic	A, B	Fabric or paper-reinforced resinous sheets, tubes and molded shapes.	Severe service insulation	0.015 to 8.000	75 to 750 ¹
Cotton Yarn	O, A	Multiple and ribbons	Wire covering, coil insulation	0.0020 to 0.010	90
Silk Yarn	O, A	Multiple and ribbons	Wire covering	0.0007 to 0.010	140
Glass Yarn	B	Multiple and ribbons	Wire covering	0.0007 to 0.010	200
Enamel	A	Film on wire	Wire covering	0.0001 to 0.0012	500

¹ Depending upon thickness (inversely proportional).

are cemented together to form flexible plates of any thickness.

The two kinds of mica most generally used for insulating purposes are: (1) Muscovite, usually called white or India mica, and (2) phlogophite, generally called amber mica. White mica withstands temperatures up to 500° C.; and amber mica, up to 800° C.

Mica, probably the most valuable insulating material in general use, has the following characteristics: (1) high insulation resistance; (2) high dielectric strength; (3) High mechanical strength; (4) Good flexibility; (5) low moisture absorption; (6) Comparatively good heat conductivity; (7) Low deterioration from heat; (8) Excellent resistance to acid; (9) A specific inductive capacity, or dielectric constant, from 4 to 8; (10) Low dielectric loss or power factor (2 to 5 per cent).

Thin paper or cloth backing for mica, with a bond of shellac, asphalt, or synthetic resins, make possible flexible mica in the form of tape, coil wrappers, and tubes. For hot or cold molding, white mica may be bonded with a thermoplastic material. Mica can be used in conjunction with other insulating materials, such as fish paper, rope paper, or kraft paper, for sheet insulation, or for special purposes.

Asbestos.—When used for insulation purposes, asbestos generally takes the form of paper or paper tape, asbestos millboard, or asbestos lumber, and in such forms it may contain from 10 to 20 per cent of wood pulp and glue, which give it strength. Chrysotile asbestos can be spun and made into asbestos cloth or cloth tape, which usually contains about 14 per cent cotton. Selected long-fiber material is made into 100 per cent asbestos twine.

While asbestos is a very poor electrical insulator, it is excellent for absorbing insulating compounds. When dry and properly treated, is valuable for high temperature insulation, and for the dissipation of corona in high-voltage apparatus. It is also one of the few fabrics that

cannot be destroyed by termites. Flexible cords used with domestic heating appliances, such as flat irons, have an asbestos covering between the rubber insulation over the conductors and the outer braid. This construction makes the cord fire resisting.

Fibreglas.—This electrical insulating material is woven from two kinds of yarn: continuous filament, and staple fiber. Continuous filaments, or fibers, are produced by mechanical drawing of the molten glass into fibers of great length (measured in miles); they have a general resemblance to natural silk or rayon in the manner in which they are later processed. Staple fibers are produced by steam drawing of molten glass into fibers varying from 8 to 14 inches in length, which have a general resemblance to cotton or worsted fibers.

Both fibers are inorganic, incombustible, durable, nonabsorbent, and relatively nonhygroscopic—properties commonly associated with the glass from which the fibers were made. In addition they are resilient, extremely flexible and have extraordinary unit tensile strength, exceeding that of the strongest piano wire—properties peculiar to glass in the form of fine fibers.

Fibreglas cloth is used as a base in the fabrication of varnished cloth, or cambric, and as a backing for mica. It is available in full cloth width, or cut into narrow tapes. A complete line of Fibreglas-mica cloths and tapes is also available.

Fibreglas also serves as a base for material of laminated products, available in a variety of thicknesses which can be machined or formed into intricate shapes as required. All Fibreglas products are used for electrical insulation in the same manner as any standard textile product.

Fibreglas electrical textiles successfully withstand temperatures in excess of 1,000° F. without impairment of their electrical properties, and they withstand temperatures in the neighborhood of 650° F. before losing their original flexibility and resiliency.

Individual glass fibers are relatively nonhygroscopic and nonabsorbent—properties of major importance in many electrical applications. Fibreglas electrical insulation is resistant to external abrasion, and to attack by moisture, acids, oils, and most corrosive vapors. The high insulation resistance (the ability to resist the flow of current through or over the surface of an insulating material) of Fibreglas impregnated tapes is substantially in excess of that of cotton or asbestos materials of similar character.

Because Fibreglas electrical yarns and tapes combine high temperature resistance, exceptional electrical properties, and great tensile strength, they permit the design of many types of electrical equipment in which the amount of insulation material used is substantially reduced.

Cotton.—Like all other organic materials, cotton is not adapted to the high-temperature applications which inorganic materials satisfactorily withstand. However, cotton is widely used for electrical insulating purposes in various forms of fabrics. Such fabrics are usually processed with different varnishes, gums, or compounds. Some of these composite materials have highly valuable insulating properties.

Untreated materials are used to a great extent for oil-type transformer insulation. They are thoroughly dry when immersed in the oil, which rapidly impregnates all fibers, resulting in an insulating material acquiring excellent physical properties from the cotton and dielectric strength from the oil.

The fundamental Class A materials are treated, or "pretreated" fabrics, of which there are numerous varieties. The two kinds in most common use are tan-linsed oil, or tung oil varnish-treated cloths; and black varnish, and asphaltum or bitumen compound treated cloths.

When tested in sheet form between two-inch circular electrodes, the instantaneous breakdown voltage of the tan-varnished cloth will usually be not less than 1,000 volts per mil; of the black cloth, 1,200 volts per mil.

Silk.—The insulating properties of silk are about the same as those of cotton. Because of its strength and smooth finish, silk is used principally to insulate magnet wire. Its cost is higher than that of cotton, and it is not generally used, except where space is an important factor, silk materials being thinner than cotton.

Adhesive or Friction Tape.—This cotton fabric insulating material is treated with a viscous rubber or bitumen compound; it is not often used as insulation for electrical apparatus, except in coil end connections of low-voltage induction motors, where it is completely covered with varnish or shellac. When fresh and in good condition, it may possess a dielectric strength of about 100 volts per mil, but it deteriorates rapidly when exposed to air.

Insulating Paper and Pressboard.—These materials are used extensively for insulating purposes in some types of electrical equipment such as transformers, circuit breakers, motors, and generators. However, for such insulating purposes, special papers not subject to rapid deterioration are required. These papers are made from pure cotton rag, Manila fiber, and purified chemical wood pulp.

Insulating papers vary from thin tissues to "fish" papers, thick pressboard, and Fullerboard types. Untreated paper has a tendency to absorb moisture, and has little insulating value where

moisture may penetrate, but when impregnated with varnish, oils, or compounds, its high dielectric strength, high insulation resistance, and other valuable insulating properties are maintained.

Paper is used for the insulation of magnet wires and high-voltage cables, and is often used in combination with other insulating materials, such as mica, in making insulating tapes.

Insulating papers for wire are made in three general types, known as Standard, Flexrope, and Super Flexrope. The differences in the three grades lie in the quality of softness, Standard being the most hydrated and therefore the hardest. All three types have a 100 per cent rope content. Other grades contain varying percentages of rope, the remainder of the material used being sulphate wood pulp or cotton fiber. Power-cable insulation is made of 100 per cent Manila fiber, or of 100 per cent sulphate wood pulp, and is not stocked in mixtures of these materials. Some grades are tinted in various colors for identification purposes.

Uses of Insulating Papers.—

(1) Insulation of magnet wire, enameled or bare, both in combination with cotton insulation, or alone.

(2) Insulation for transformer coil wire—dry or liquid-filled types—flat, square, or round.

(3) Lamp-cord insulation, to replace cotton and prevent corrosion of copper by rubber, also to permit easy stripping of insulation.

(4) Insulation of telephone wires in lead-covered cable: (a) as insulation of individual wires, (b) as core wrapping, where paper jackets the cable as a whole rather than individual wires.

(5) Insulation of high-voltage cables.

(6) Insulation of battery cables, automotive wire, and service-entrance cable.

(7) Mica-tape paper.

(8) Capacitor paper.

Motor slot and miscellaneous insulation is available in thin sheets, or in rolls of high-density press paper made of cotton, mixtures of cotton and purified chemical wood pulp, and 100 per cent Manila fiber.

Formex.—Known by its trade name, this modern development in insulation consists of a round magnet wire, the insulation of which is provided by a layer of high-grade paper, bonded or cemented over a very high quality enameled wire. It possesses more than 50 per cent greater dielectric strength than other insulated wires. The over-all size of the insulated conductor is smaller than that of conventional insulation. It therefore enters slots easier, permitting the use of more copper in a given slot area.

Varnishes.—A liquid form of insulation applied to tape, mica, and other materials to give additional electrical protection, and also to give added protection from moisture, oil, and dirt.

In the early days of the electrical industry, shellac and other gum solutions were the only materials available for electrical insulation. Shellac was soon found to be unsatisfactory for many reasons, prominent among which were: (1) brittleness, which caused cracking and flaking off; (2) permeability, which resulted in electrical breakdown in the presence of moisture; and (3) thermoplasticity, which caused the dried film to flow when subjected to heat.

Later, combinations of pitches, asphalts, and gums with drying oils were made available in a wide variety of grades to meet the ever-changing

demands of the electrical industry. Also, it has often been found possible to blend two insulating varnishes having different characteristics to produce a third varnish having characteristics not found in either of the two. Instead of the narrow choice available in the early days of the industry, modern electrical men have a choice of clear and black varnishes, air-drying and baking varnishes, finishing varnishes, oil-proof enamels in various colors, synthetic gum-base varnishes, and many others.

Raw Materials Used.—The chief raw materials used in the manufacture of insulating varnishes may be listed as follows:

Oils: tung oil, linseed oil, soybean oil, oiticica oil, perilla oil, castor oil, and fish oil.

Gums: (natural) rosin, copal, congo, kauri.

Gums: (synthetic) phenol formaldehyde, glyceryl phthalate, maleic, ester, polyvinyl, coumarone, araclor, urea formaldehyde.

Asphalts: gilsonite, manjak, grahamite, Trinidad, and petroleum residues.

Pitches: vegetable, coal tar, animal, and marine.

Driers: lead, cobalt, manganese, zinc, and vanadium are used in conventional varnishes as resinates, linoleates or tungates. The naphthanates of lead, cobalt, manganese, and zinc are used in most synthetic gum-base varnishes.

Thinners.—Benzine (VM & P naphtha, a petroleum derivative), mineral spirits, denatured alcohol, coal tar solvents.

The petroleum solvents are preferred for baking varnishes. Coal tar solvents are sometimes used, but these should not be used when the varnish is to be applied directly over enameled wire. Some of the synthetic gum-base varnishes require a special solvent, in which case it is best to procure this article directly from the varnish manufacturer. If the wrong solvent is used, the solid content of the varnish may be thrown out of solution, the drying retarded, or the finish impaired.

Removing Moisture.—All cotton, silk, and paper covered wires absorb and retain a certain amount of moisture. When units wound with these types of wires are to be treated with insulating varnish, the moisture must be removed and replaced with varnish. If allowed to remain, this moisture would eventually damage the insulation and cause electrical breakdown.

To remove the moisture, it is necessary to preheat the unit to a temperature preferably above the boiling point of water. A temperature of 240° F. is usually regarded as standard. The length of time that units should be preheated depends on the size of the unit and the depth of the winding. A minimum of two hours should be allowed. Any air remaining inside the windings will be expanded considerably, as it will be at a temperature of 240° F. On immersion in the varnish, this air will cool and contract, thus drawing additional varnish into the windings. The heat imparted by preheating also tends to drive off solvents from inside the windings, and helps to insure an even bake throughout.

Uses for Insulating Varnishes.—There are many uses for the various types of insulating varnishes that are on the market.

Baking Varnishes.—These varnishes should be used, when possible, for new coils and windings, as they give much greater flexibility. Because they dry more thoroughly, there is less danger of solvents being trapped. Some air-drying var-

nishes will "skin" in the can, so on voids they will "surface seal" and trap solvents unless great care is used. There are times when the dimensions of the unit to be varnished are such that adequate oven space is not available for baking.

In this case a carefully selected air-drying varnish may be used. This type of varnish must be carefully applied. If a heavy coat is required, several thin coats are better than one thick coat, and each coat should be allowed to dry thoroughly before applying the next. A baking varnish is also preferable in repair work, although an air-drying varnish may be used; but it must be remembered that the life, flexibility, and resistance to oils, alkalies, and acids, will not equal that of a baking varnish.

Air-Drying Varnishes.—Widely used as finishing varnishes, for extra protection, are air-drying varnishes. An air-drying varnish such as Synthite No. 924, applied over an oilproof varnish, affords a greater protection against alkalies. Air-drying varnishes are also used a great deal in emergency rush work.

Finishing or Spirit Varnishes.—These varnishes are used chiefly for preventive maintenance work. A periodic coat of spirit varnish will fill cracks and seal defects that occur in the original insulation. A finishing varnish is often applied over a nonoilproof air-drying varnish, thus giving it an oilproof surface.

Oilproof Enamels.—This enamel is generally used on commutator end bars, V-rings, and string bands to prevent any creepage of oil from the bearings to the windings. There are two types in general use, the quick-drying alcohol solvent grades, and the slow-drying flexible grades. The latter has greater flexibility, and is used on coils where expansion and contraction prohibit the use of any varnish giving a brittle surface.

Synthetic Gum-Base Varnishes.—These varnishes serve many purposes. Some produce a hard finish which holds the wires in one solid mass, thus preventing any movement of the wires in the slots of a high-speed armature, and eliminating internal short circuits, or throwout. A varnish of this type may be used in deep coils while they are being wound; a coat is applied with a brush to each layer, and when it is baked, no wet varnish is trapped in the coil, as occurs in the use of conventional baking varnishes.

Other grades are so formulated that a second coat may be applied after the first coat has been baked for a short period; the oil is dipped, drained, and baked for one hour, then a second coat is applied, and finally a full bake is given. This method saves time and money. Many of these varnishes also afford exceptionally good protection against chemical corrosion, and some provide very high dielectric strength.

Insulating Compounds.—This type of material falls into three main classifications:

Impregnating Compounds.—While chiefly used to fill voids in certain types of coils, particularly when the voids are too large to be filled successfully with varnish, these compounds are also applicable where an extremely heavy coating is required over the winding of a coil. Although these compounds can be applied by dipping, they are often applied by the vacuum-and-pressure-impregnating process.

Filling Compounds.—One type of these compounds is used to fill in between coils and containers, for example in certain types of transformers, such as radio and neon sign transformers.

Other types are used for cable splices, potheads, and bifurcating boxes. Still other types are designed for filling countersunk screwheads, and for other such purposes, in switchboards and panels.

Stator Compounds.—These compounds differ from the two foregoing classifications in that they are supplied in a semifluid state, and are either air dried or baked. They are applied to the exposed ends of stator coils with a trowel, or putty knife, to provide a solid, impervious seal. If the implement with which they are applied is repeatedly dipped in benzine, a smooth finish will result. Certain types of stator compounds are furnished at a consistency that allows them to be applied with a brush.

Plastics.—Since the invention of Bakelite in 1909, plastics have played an important part in electrical insulation. Plastics are used in practically all electrical devices, and have given the designer and user of such equipment many advantages over older insulating materials. Plastics provide not only insulation, but also a means for supporting or mounting electrical devices, in which capacity they take the place of wood, slate, porcelain, marble, and other materials formerly used. There are many plastics available having desirable characteristics for insulation. They are as well established as solid insulation, and give great promise for the insulation and protection of wires and cables. The more important plastics are listed in Table 2.

portant part of all electrical equipment. In the group are many different grades and types, but they are all related because they employ the same or similar ingredients combined in a different manner.

Each of the materials is made of a filler (or base) and a binder. The fillers used are cotton, glass fibers, asbestos fabrics, paper, and mica flakes. The binders are numerous types of synthetic resins, varnishes, shellacs, and gelatinizing chemical compounds, such as zinc chloride. There are many different types within these classes of fillers and binders which permit almost unlimited selection for controlling the properties of laminated products.

Laminated insulating materials are produced in sheet, rod, and tube form. An unlimited variety of insulating parts for electrical equipment can be fabricated from these basic forms by machining, forming, and punching methods. The outstanding characteristics which account for the widespread use of this class of insulating materials are: dielectric strength, power factor, water resistance, mechanical strength, light weight, and toughness. Other desirable properties such as resistance to chemicals, vibration-damping capacity, and the low coefficient of friction, are responsible for many other uses of these materials, in which electrical insulation is not a primary requirement.

Vulcanized fiber is made by laminating sheets of rag paper treated with zinc-chloride solution

TABLE 2—SYNTHETIC MATERIALS WITH PROMISING CHARACTERISTICS AS ALTERNATIVES TO RUBBER FOR WIRES AND CABLES FOR INSULATION

Material	Chemical Type	Remarks
Buna S	Butadiene Polymer	Vulcanizable. Rubber-like. Copolymer with styrene. Extrudable.
Butyl Rubber	Hydrocarbon Polymer	Vulcanizable. Extrudable.
Ethyl Cellulose	Cellulose Derivative	Thermoplastic. Extrudable.
Hycar EP	Butadiene Polymer	Vulcanizable. Rubber-like. Copolymer. Extrudable or calendered strips.
Polythene	Ethylene Polymer	Thermoplastic. Extrudable.
Polystyrene-Rubber	Styrene Polymer with Rubber	Mix with rubber and vulcanize. Extrudable.
Saran	Vinylidene Chloride Polymer	Thermoplastic. Applicable as threads or tapes.
Styron	Styrene Polymer	Thermoplastic. Not extrudable. Threads or tapes.
Tenite II	Cellulose Derivative	Thermoplastic. Extrudable. Cellulose-acetate-butyrate.
Vistanex	Isobutylene Polymer	Not vulcanizable. Rubber-like. Mixed with resins or rubber. Extrudable.
<i>For Jacket or Covering</i>		
Chemigum	Butadiene Polymer	Vulcanizable. Rubber-like. Copolymer. Extrudable or calendered strips.
Hycar OR	Butadiene Polymer	Vulcanizable. Rubber-like. Copolymer. Extrudable or calendered strips.
Perbunan	Butadiene Polymer	Vulcanizable. Rubber-like. Copolymer with acrylonitrile. Extrudable or calendered strips.
Thiokol	Organic Polysulfides	Both thermoplastic and vulcanizable types. Extrudable.
<i>For Insulation or Jacket</i>		
Koroseal	Plasticized Vinyl Chloride Polymer	Thermoplastic. Extrudable.
Neoprene	Chloroprene Polymer	Vulcanizable. Rubber-like. Extrudable or calendered strips. Several types.
Vinylite	Plasticized Vinyl Chloride Polymer	Thermoplastic. Extrudable. Copolymer with vinylacetate.

A very important plastic insulating material known as the *silicon resins* offer great possibilities for electrical insulation. They are well adapted to this use, and superior to all other insulating materials where thermal aging or excessive moisture are encountered. Silicones are used primarily as a varnish or binder. The use of silicon resins will make it possible to operate electrical machinery, such as motors and generators, at higher temperatures than ever before, and will accordingly reduce their size for a given output.

Laminated Insulating Materials.—This large group of materials forms an essential and im-

portant part of all electrical equipment. In the group are many different grades and types, but they are all related because they employ the same or similar ingredients combined in a different manner.

The dielectric strength of fiber may be reduced as much as 75 per cent after prolonged exposure to humid atmosphere. Under no cir-

cumstances should it be used as an insulating material where even occasional immersion in water is likely to occur.

Fish paper insulation is an exceedingly tough insulating paper developed primarily as an insulation for armature slots and field coils. Extra strong fibers are used, and the chemical treatment, which is somewhat different from that used in the manufacture of vulcanized fiber, insures those qualities which are most essential in an insulating paper. Such insulation is made in sheet and continuous rolls, or in ribbon rolls for automatic machines. It is furnished in a natural dark gray color only. In manufacturing electrical equipment, fish paper insulation is used in armature wedges, slot insulation, attachment plugs, brush backs, brush-holder bushings, bushings, casings for enclosed fuses, commutator rings, insulation for armature and field coils, ignition cable tubes, panel boards, push buttons, switch bars, arc chutes, interpole barriers, rail and trolley insulation, and grommets.

Fiber may also be treated during the process of manufacture with special waterproofing resin. Fiber thus treated possesses characteristics which qualify it for many uses in the electrical industry. It is hard, and will resist abrasion; it is dense, tough, and strong; it has high dielectric strength; it has good arc resistance, but not so much as has untreated fiber; it is easily machined; and it resists moisture better than does untreated fiber.

Laminated insulation in tubular form, which is widely used, is made by impregnating special kraft paper with resin and shellac mixtures, and by subsequently heating it under pressure. Such tubes are more resistant to arcing than most synthetic resinous laminated materials, and they possess excellent dielectric properties. These tubes are used for bus insulation, cable joints, wall bushings, supports, transformer tank linings, motor and generator brush holders, collector rings, coil supports, and for other such purposes.

Insulation for Transformers and Circuit Breakers.—Insulation used for transformers and circuit breakers is usually made up in sheets of layer insulation, for small spaces, and for encircling the entire core in transformers. Most insulation of this sort consists of new cotton cuttings and purified chemical wood pulp, and is made up in the following three grades: (1) 100 per cent cotton rag; (2) 75 per cent cotton rag, 25 per cent purified chemical wood pulp; and (3) 50 per cent cotton rag, 50 per cent purified chemical wood pulp.

Commutator Insulation.—Either white or amber mica is used for commutator insulation. However, if white mica is used for commutator segments, it is necessary to undercut the segment, as the copper bars wear faster than the mica, thus causing a rough surface and a pitting of the bars. To offset this disadvantage, white mica plate is usually less expensive than amber. Amber mica, however, is sufficiently soft to afford even wear with the copper bars, and for this reason undercutting is not usually necessary.

Consulting Engineer.

INSULIN, ɪn'sū-līn, one of the class of substances called hormones, which have the peculiar function of exciting action in some other organ of the body, at a greater or less distance. The duty

of the hormone insulin is to regulate the metamorphosis of sugar (glucose) into fat. In the absence or insufficiency of insulin, the excess of sugar is found to be forced into the urine, and also is deposited in the muscular tissue of the heart, and the diseased condition known as diabetes results. Insulin is a product of those parts of the pancreas known as the islets of Langerhans, from their discoverer, and was isolated first by Dr. F. G. Banting, of the University of Toronto, and thus made available as a remedial agent in the treatment of diabetic conditions. As the insulin must become a part of the blood stream to accomplish its function, the present treatment is by way of hypodermic injection, administered by a physician. Efforts are being made to devise some insulin-carrying substance which can make its way into the blood stream when taken by the mouth, as are other medicines. Chemically, insulin is a proteose substance, with the formula, $C_{90}H_{150}O_{24}N_{22}S_2$. See also DIABETES MELLITUS; MEDICINE, HISTORY OF —11. *The 20th Century* (Endocrinology).

Consult Haugaard, N., and Marsh, J. B., *Action of Insulin* (Springfield, Ill., 1953).

INSURANCE, ɪn-shōōr'āns, the act whereby for a consideration (the *premium*), one party (the *insurer*) binds himself in a contract (the *policy*) to indemnify or guarantee another (the *insured*) against loss through the happening of a specified contingency (the *risk*). The device of insurance is one of the important safeguards developed for eliminating or reducing loss to the individual arising from certain kinds of risk. Moreover, in providing protection against potential loss, it performs a social function even if no loss occurs, this function serving notably in circumstances where credit is used. Reduction or prevention of loss also is an objective to which the activities of the insurance business increasingly are directed.

Risk may be defined as the chance of loss (though the word is used commonly also to refer to the subject of the risk); hazard, as the cause or source of the loss. Risks are estimated according to the expectation of loss and may be classified with respect to their nature into: (1) *physical risks*, depending on age, health, condition, location, structure, occupancy, and exposure; and (2) *moral risks*, arising from such mental conditions as motivate dishonesty, negligence, and insanity. Hazards may be: (1) common to all in a community, as price changes, wars, and windstorms; or (2) restricted to individuals, as occurrences causing loss or injury to one's self or property, or causing loss or injury to another or his property.

Except in self-insurance, the basis of insurance is the pooling of risks by the transfer of individual risks to a group. The insuring group, or carrier, may be an association, a corporation, or a government. In order to continue its function, it must collect funds sufficient to pay losses and expenses. To do this successfully the aggregate of risks so transferred must be large in numbers and widely spread. The method of weighing the risk and fixing the premium is based upon the *law of large numbers* as used to apply the *theory of probabilities*. This law is derived from the observation that the larger the number of instances taken, the closer the result approximates the theoretical probability. In certain lines of insurance the nature of the risks

permits the calculation of elaborate and precise tables.

With respect to the kind of subject matter insured, insurance may be divided broadly into: (1) *personal insurance*, including life, disability, and social insurance; and (2) *property insurance*, including fire, marine, casualty, liability, and fidelity insurance, and suretyship. In point of priority, the practice of marine insurance long preceded insurance against fire and upon lives. In our modern conception of the term it existed among Italian traders before the year 1400, and was introduced by them to London. There the organization of underwriters at Lloyd's began to operate shortly after 1688. In America, marine insurance has been available since the early 1700's. Though life insurance policies were issued in England in the latter part of the 16th century, such insurance did not become common until after 1700. The first corporation for insuring lives in America was the Presbyterian Ministers' Fund, chartered in 1759, but the real growth of life insurance in the United States did not come until after 1850. Fire insurance dates from the great fire of London of 1666, and in the following century a number of companies were organized in America to write this type of coverage. The various lines of casualty insurance are of more recent origin, the youngest important one being aviation insurance. In this, Lloyd's wrote the first policy in London in 1912, and their underwriting agency in America was the first there, 10 years later.

In the United States in 1956 there were approximately 1,144 legal reserve life insurance companies, fraternal orders, and assessment associations; in addition 288 banks were writing savings bank life insurance in the states of Massachusetts, New York, and Connecticut, where this type of life insurance is permitted by law. Operating in the fire and allied lines and marine fields there were approximately 400 stock companies and 2,600 large and small mutual companies. Of the fire and allied lines stock companies, 227 were National Board of Fire Underwriters members. In the same field there were 64 reciprocal and interinsurance exchanges and 14 American Lloyds organizations. There were approximately 223 stock and 140 mutual companies writing casualty and surety insurance, with an estimated 30 reciprocals, interinsurance exchanges, and American Lloyds. In addition there were approximately 90 assessment accident and health insurance associations. A large number of Blue Cross and Blue Shield medical care and hospital service plans have been organized since World War II.

In 1955, on the recommendation of the National Association of Insurance Commissioners, enabling legislation was enacted in all states of the United States to permit fire and casualty insurance companies to engage in full multiple-line underwriting. Multiple-line underwriting means that a single fire or casualty insurance carrier may underwrite several classes of insurance, except life. The result has been the merger of many fire and casualty companies, or the purchase of one type of company by the other to operate as a separate entity.

Apart from private enterprises, various governments and governmental agencies in the United States engage in a fairly wide range of insurance, quasi-insurance, and pension plans. State and local activities include workmen's compensation

funds, public property insurance funds, a small state life insurance fund (Wisconsin), hail insurance in three states (North Dakota, Montana, and Colorado), and a large number of pension systems for teachers, firemen, and other public employees. The operations of the federal government in this general field are broad. There are pension funds for war veterans and federal employees, an unemployment insurance plan, a system for retirement and unemployment benefits for railroad employees, indemnification plans for bank and building loan accounts, and crop insurance. The Social Security Act was passed in 1935, and under its amendment of 1939 the system of old-age and survivors insurance was inaugurated. In 1956 the law was further amended to include provisions for optional retirement age (62) for working women, an earlier option for wives of retired workers, and earlier benefits for widows. The amendments also provided for certain disability benefits to covered persons.

The government's first plan of life insurance for members of the armed forces, the United States Life Insurance, was instituted during World War I, and in 1940 the National Service Life Insurance was provided for those in World War II. In the latter war, the government also sponsored the War Damage Corporation in writing policies of protection against enemy attack.

In 1954 a federal employee group life insurance plan was created by a special act of Congress. It was the largest single group plan ever written, covering two million federal government employees in the United States for a total of \$10.1 billion in 1956. This vast program was underwritten by the life insurance companies.

Supervision and regulation of insurance companies were administered exclusively by the several states until 1944, when the United States Supreme Court held that the business of insurance is commerce and that, when its activities cross state boundaries, it is interstate commerce and thus subject to regulation by Congress under the commerce clause of the federal Constitution.

As a business institution, insurance performs important services in American economic and social life. Its scope may be appreciated from the following data. On Dec. 31, 1946, the total assets held for the benefit of policyholders by all legal reserve life insurance companies in the United States were estimated at \$96.25 billion; those of the stock and mutual fire and marine companies, over \$4 billion; and those of the stock and mutual casualty companies, over \$3 billion. On the same date, the life insurance companies carried insurance in force of over \$412.63 billion. The coverages written by the fire, marine, casualty, and surety companies, by their very nature do not readily yield estimates of the total liabilities assumed.

Investments comprising the assets of American insurance companies are a cross section of the economic life of the nation. They are widely diversified not only as to kind, maturity, industry, and company, but geographically as well, within the United States and Canada. This diversification has not only meant greater safety for policyholders, but has also served the useful purpose of bringing to many sections of the country a more adequate supply of capital than would be available locally. Of special importance is the increasing interest developed in housing

projects; though the tendency was initiated by the larger companies, the smaller ones have also entered the field. See also separate articles on the various types of insurance mentioned, such as FIRE INSURANCE; HEALTH INSURANCE; LIFE INSURANCE; and others.

**DISTRIBUTION OF ASSETS, ALL UNITED STATES
LEGAL RESERVE LIFE INSURANCE COMPANIES**
Estimated Dec. 31, 1956
(millions of dollars)

	Amount outstanding	Per cent of total
Bonds		
United States government	\$ 7,600	7.9
*State, county, and municipal	2,250	2.3
*Canadian government	1,050	1.1
*Other foreign governments	50	.1
Total government	10,950	11.4
Railroad	3,900	4.0
Public utility	14,500	15.1
Industrial and miscellaneous	19,900	20.7
	49,250	51.2
Stocks		
Railroad	150	.2
Public utility	1,400	1.4
Other	2,100	2.2
	3,650	3.8
Mortgages		
Farm	2,500	2.6
Other	30,600	31.8
	33,100	34.4
Real Estate	2,850	3.0
Policy loans and premium notes	3,500	3.6
Cash	1,200	1.2
Other assets	2,700	2.8
Total assets	96,250	100.0

*Includes turnpike revenue bonds. †Includes all political subdivisions. Source: Institute of Life Insurance and Life Insurance Association of America.

INSURANCE TERMS

Words of precise meaning used to define insurance contracts, or used in connection with such contracts follow:

Abandonment.—In ocean marine insurance, the exercise by the insured of his right, in the event of constructive total loss, of relinquishing to the insurer the salvage in order to establish a claim for total loss.

Abordage.—In ocean marine insurance, the obligation of the insurer of a ship damaged by another ship through collision on the open sea to indemnify the insured for the loss, with right of recovery at civil law against the party causing the damage.

Acceptance.—In general, the validating act to insurance contract by the insurer in agreeing to accept for a specified premium a risk offered for insurance. In ocean marine insurance the act of the insurer that perfects the rights of the insured in the recovery of his loss when he has offered abandonment.

Accident Insurance.—Indemnifies for bodily injury or death caused by accident, including loss of time from occupation, and hospital, nurse, surgical and medical expenses. See also separate article **LIABILITY INSURANCE**.

Accounts Receivable Insurance.—Indemnifies for loss through inability to collect accounts because of damage to, or destruction of, records.

Actuary.—In insurance, the official in an insurance company whose function is to make the mathematical calculations necessary to maintain the business on a sound financial basis; these include the valuation of contingent liabilities, the computation of risks, the construction of premiums, and the determination of various items as reserves, loss ratios, dividends, and nonforfeiture values.

Agreement.—In insurance, a contract written or oral between the insurer and the insured made before the issuance of the policy. It embodies an understanding on essential provisions.

Agricultural Insurance.—See article **CROP INSURANCE**.

Agricultural Machinery and Equipment Insurance.—Under an inland marine insurance policy it provides coverage on mobile agricultural machinery and equipment (not on sale or consignment, or in course of manufacture), which has come into the custody or control of parties who intend to use

such property for the purpose for which it was manufactured or created.

Aircraft Hull Insurance.—Indemnifies for loss or damage to aircraft or parts thereof arising from all risks or specified perils.

Aircraft Liability Insurance.—Covers legal liability of owner or operator of aircraft for bodily injury, death, or property damage arising from ownership, maintenance, or use of aircraft covered by the policy.

Aircraft or Vehicle Property Damage Insurance.—Indemnifies for damage to property resulting from collision with, and caused by, aircraft or objects falling therefrom, or other vehicle, not owned by insured.

Aircraft Personal Accident Insurance.—Indemnifies passengers or pilots for bodily injury or death caused by aircraft accident.

Airmen's Liability Coverage.—Special form of aircraft liability insurance, providing coverage for airmen's.

Airport Liability Coverage.—Special form of aircraft liability insurance, providing coverage for airport owners and operators.

All Risks Coverage.—Insures against all risks or loss or damage directly arising from any external cause; certain forms specify exclusions.

American Experience Table of Mortality.—Shows number of people dying each year by age groups used by life insurance companies in fixing premium rates.

Annuity Policy.—Provides income to one or more persons for life or for a specified period. Different forms are available to meet particular needs; with the exception of the *annuity certain*, which continues for a specified time regardless of any contingency, annuity payments are contingent on the happening of some agreed event, as the first death of a number of beneficiaries in a *joint life annuity*, or the last death of a number of beneficiaries in a *last survival annuity*. Payments are made at fixed intervals.

Assessment.—In ocean marine insurance, the contribution apportioned among the various interests in general average. In mutual insurance companies, a call upon premium notes given by members as a substitute for the investment of paid-up stock.

Assessment Insurance.—A form of life insurance written by certain fraternal societies or associations wherein the premium payments are not fixed in the policies but determined by the insuring organizations as the needs to meet claims require.

Assigned Accounts Bond.—Guarantees that borrower will apply to reduction of loan collections from accounts receivable pledged as collateral.

Automatic Coverage.—Operates to include change in subject matter insured or its location without notice to insuring company.

Automobile Insurance—Damage to One's Own Car.—Indemnifies owner for loss or damage to his automobile or its contents. See also separate article **LIABILITY INSURANCE**.

Automobile Liability Insurance.—Covers legal liability for bodily injury, death or property damage arising from ownership, use, or maintenance of any automobile covered by the policy. Medical payments coverage may be included at the option of the insured. It provides for payment of all reasonable expenses incurred within one year from date of accident for necessary medical, surgical, dental, ambulance, hospital, professional nursing and funeral services to or for each person injured while in, upon, entering or alighting from the automobile covered by the policy, and to or for each insured injured through being struck by an automobile. See also separate article **LIABILITY INSURANCE**.

Automobile Nonownership Liability Coverage.—Extension of coverage of automobile liability insurance to include legal liability of insured arising from use by his employees in his business of automobiles not owned by him. See also separate article **LIABILITY INSURANCE**.

Average Clause.—See term *Coinurance or Average Clause*.

Aviation Insurance.—A class of insurance comprising aircraft hull, aircraft liability, and aircraft personal accident insurance.

Bail Bond.—Assures appearance of arrested person or payment by surety of penalty.

Bailee's Customers' Floater.—Provides coverage for laundries, dyers, cleaners, tailors against loss or damage to customers' property during processing on premises, or in transit.

Bailee's Liability Insurance.—Covers legal liability of custodian of goods of others for loss or damage by named perils, excluding those of improper processing.

Bankers' Blanket Bond.—Provides coverage for financial institutions against loss arising from dishonesty of employees, burglary, inside or outside robbery, and also from forgery if this additional coverage is purchased.

Barratry.—In ocean marine insurance the willful commission of any unlawful or fraudulent act or breach of duty in the management of a ship or its cargo to

- the injury of the owner and without his consent.
- Bid Bond.**—Guarantees that bidder on contract will undertake contract if it is awarded to him.
- Binder.**—Form protecting insured till policy is issued, and subject to policy's conditions.
- Blanket Policy or Form.**—Covers several properties or risks in one instrument.
- Blanket Position Bond.**—A fidelity bond covering all employees insured, each separately for uniform amount, new or substituted employees being automatically covered.
- Boiler and Machinery Insurance.**—A class of insurance comprising a number of liability and direct damage coverages against loss, damage, bodily injury, or death caused by boiler or machinery accidents.
- Brokers' Blanket Bond.**—Provides coverage for securities brokers similar to that of bankers' blanket bond.
- Burglary Insurance.**—See separate article **BURGLARY INSURANCE**.
- Business Interruption Insurance.**—Indemnifies for operating expenses continuing, and profits not earned, during period when business is interrupted by risk insured against.
- Capital Sum.**—Amount or portion thereof payable in accident insurance policy upon specified disability caused by accident.
- Cargo Insurance.**—Covers merchandise during ocean transportation together with shore and inland risks incidental thereto.
- Cash Surrender Value.**—Amount receivable by life insurance policyholder when he cancels his policy or permits it to lapse; it is an optional nonforfeiture value.
- Casualty.**—A term frequently used in insurance as a synonym for accident.
- Casualty Insurance.**—A general class of insurance embracing those forms that indemnify insured for certain kinds of losses caused by accident to his own person or property, and those that cover his legal liability to others for bodily injury, death, or property damage.
- Coinsurance.**—Sometimes known as the **REDUCED RATE CONTRIBUTION or AVERAGE CLAUSE**, it is applicable to property damage insurance of various kinds but is most prominent in fire insurance. Its purpose is to distribute equally the cost of insurance over the insuring public in proportion to individual valuations which are also appraised for relative hazards. Provides that the insurer shall be liable in the event of loss for not more than that proportion of the loss which the amount of insurance under the policy bears to the specified percentage of the actual cash value of the property insured. The percentage of coinsurance may vary but 80 per cent predominates. The coinsurance clause in the contract that the insured will maintain insurance to the extent of 80 per cent of the value of the property being insured or become a coinsurer for the difference. Thus a \$10,000 building subject to the 80 per cent coinsurance clause would require a minimum of \$8,000 insurance. In the event that only \$4,000 insurance is carried, a \$2,000 loss would receive a \$1,000 contribution from the insurance company leaving the other \$1,000 to be contributed by the insured.
- Collapse Insurance.**—Collapse insurance is now being written in many dwelling forms and under some new all-risk type forms available for commercial property. The Additional Extended Coverage Endorsement, The Dwelling Building(s) Special Form are among those containing collapse coverage for dwelling risks.
- Collision Insurance.**—In automobile insurance, indemnifies owner for damage to his automobile caused by collision with stationary or moving object. Collision coverage is provided also in other types of insurance, as aircraft or vehicle damage, aircraft hull, ocean marine, and elevator insurance.
- Comprehensive Automobile Liability Policy.**—Covers legal liability of insured arising from any hazard involved in maintenance, operation, or use of any automobile regardless of ownership.
- Comprehensive Dishonesty, Disappearance, and Destruction Policy.**—Combines coverages of primary commercial blanket bond, the two forms of money and securities policies, securities insurance policy (for lessees of safe-deposit boxes), and depositors' forgery bond; usually all or any combination of these coverages may be selected.
- Comprehensive General-Automobile Liability Policy.**—Combines coverages of comprehensive automobile liability and comprehensive public liability policies.
- Comprehensive Liability Insurance.**—A class of insurance embracing those forms that on a broad basis cover legal liability of insured for any hazard not excluded.
- Comprehensive Personal Liability Policy.**—Broad form of coverage for individual's legal liability for bodily injury or death; includes sports and residence coverages and embraces acts of insured's wife, minor children, and pets.
- Comprehensive Public Liability Policy.**—Covers legal liability of insured for bodily injury or death sustained by persons not in his employ, except liability arising from maintenance, operation or use of automobiles.
- Compulsory Insurance.**—Refers to those forms of insurance that are required by statute in certain jurisdictions. Common examples are automobile liability, workmen's compensation, and social old age and unemployment insurance.
- Consequential Damage Coverage.**—By endorsement on direct damage policy, indemnifies for indirect loss arising from accident to an insured object on premises, as from fire, explosion, or breakdown.
- Constructive Total Loss.**—May be established when cost of recovering and repairing damaged property would be commercially unprofitable.
- Contract Bond.**—Guarantees that party to a contract, commonly for construction or engineering work, will faithfully perform its terms.
- Contractors' Public Liability Policy.**—Covers legal liability of insured for bodily injury or death arising from his contract operations, including the existence of tools and equipment left or abandoned at place of work.
- Contractual Liability Policy.**—Protects insured against liability of others, which he has assumed, for bodily injury or death.
- Court or Judicial Bond.**—Assures to litigant in court pursuit of remedy, or protection to his adversary; there are many types and their forms are prescribed by law.
- Coverage.**—Denotes the protection promised against the risks specified in an insurance contract.
- Credit Insurance.**—Guarantees payment to insured of bad debt losses in excess of specified amount, with special provisions for coinsurance on certain classes of risks. See also separate article **GUARANTY INSURANCE**.
- Crop Insurance.**—See separate article **CROP INSURANCE**.
- Custodian's Bond.**—Guarantees that custodian will retain possession of property pledged as collateral by borrower till loan is repaid, with partial withdrawals authorized by lender.
- Customs Bond.**—Guarantees payment of duty and taxes on entry into United States of property from foreign source.
- Deductible Clause.**—As applied to insurance, specifies amount in excess of which the insured may recover in claim for loss.
- Deferred Insurance.**—A form in which the liability of the insurer does not begin until a specified future date.
- Depositors' and Commercial Forgery Bond.**—Provides coverage of depositors' forgery bond and also coverage against 75 per cent of insured's pecuniary loss through forgery or alteration of negotiable instruments received for goods delivered or services rendered.
- Depositors' Forgery Bond.**—See term *Forgery Bond*.
- Depreciation Insurance.**—Provides indemnity for loss measured by the difference between value of building less depreciation and cost of replacing a building of like character.
- Deviation.**—In ocean marine insurance, the voluntary departure of a vessel, without necessity or reasonable cause, from the usual course of the voyage for which she was insured; such a departure is held to be a breach of an implied warranty by the insured and terminates the liability of the insurer. On the same reasoning any unusual or unnecessary delay releases the insurer from all risks.
- Disability Insurance.**—A general class of insurance embracing those forms, as accident, and health insurance, that indemnify for loss through disability as distinguished from death.
- Discovery Bond.**—A fidelity bond covering losses discovered during life of bond though occurring previously.
- Dog Liability Coverage.**—See terms *Residence, Farm Liability Insurance; Comprehensive Personal Liability Policy*.
- Double Indemnity Provision.**—In life, accident, and health insurance, provides double the amount payable, if death or specified disability is caused through specified accidents.
- Double Insurance.**—Exists when two or more policies cover the same interest of the same insured against the same risks in proportions exceeding the sum necessary to provide complete protection. The insured may sue upon all the policies although he may obtain but one satisfaction.
- Elective Indemnity Provision.**—In an accident insurance policy, this provision grants option to insured to choose with respect to specified disabilities between receiving scheduled amounts at once or in weekly payments.
- Elevator Insurance.**—In various forms, provides coverage for legal liability of insured for bodily injury, death, or property damage arising from existence or

- use of elevator or equipment, and provides indemnity to him for damage to his own property through collision of elevator or object carried thereon with another object.
- Employers' Liability Insurance.**—Covers legal liability of employer for bodily injury or death to employees; restricted to employees not under workmen's compensation laws.
- Endowment Insurance.**—Provides for payment of policy amount at end of specified period, as 10 or 20 years, or at age 55, 60, or 65.
- Equipment Dealers Insurance.**—Designed for and issued to dealers in mobile agricultural and construction equipment, the property of the assured and the property of others in the custody or control of the assured, for sale, display, demonstration, storage, service, repair or for the purpose of performing work thereon.
- Errors and Omissions Insurance.**—Provides coverage for financial institutions with loans on mortgaged property as collateral, against loss arising from inadequate insurance on such property resulting through error.
- Excess Commercial Blanket Form.**—Provides fidelity coverage in excess of primary coverage on schedule or blanket forms.
- Excess Indemnity Endorsement.**—On blanket position bond, provides fidelity coverage against loss caused by employees in any positions selected in excess of primary coverage.
- Expense Loading.**—Portion of premium calculated to meet insured's share of the operating expenses of the insuring company.
- Extended Coverage Endorsement.**—Extends fire insurance coverage to include windstorm, hail, explosion, riot, aircraft, motor vehicle, and smoke damage. The purpose is to market all of these coverages under a single policy. Additional Extended Coverage Endorsement is a form attachable to a fire insurance policy, provided the Extended Coverage Endorsement is also attached. Available only for dwellings, the form provides coverage for the perils of water damage, explosion of steam boiler, vandalism and malicious mischief, vehicle damage by owned vehicles, fall of trees, objects falling from weight of snow, freezing of plumbing, collapse, landslide, breakage of glass. (Coverage of landslide has been deleted in some jurisdictions.)
- Extended Term Insurance.**—Provides coverage to life insurance policyholder in policy amount for such period as would be purchased by the cash surrender amount used as single premium payment; it is an optional nonforfeiture value and usually operates automatically if holder does not select a different nonforfeiture value.
- Extra Expense Insurance.**—Protects any type of organizations which cannot afford to have its business interrupted by fire but must incur whatever additional expense is necessary to maintain operations constantly. It should not be confused with Business Interruption Insurance.
- Fidelity Bond.**—Indemnifies employer for loss of property, owned by him or in his custody, through dishonesty of his employees.
- Fiduciary or Probate Bond.**—Guarantees faithful performance of court orders, and of official duties, as collection, safekeeping, distribution, and accounting, by official, as executor, administrator, trustee, receiver, appointed by court to administer estate funds.
- Fine Arts Floater.**—Indemnifies for loss or damage to scheduled objects of art, in named or any location, arising from all risks with exceptions, and from named perils.
- Fire Insurance.**—Indemnifies for stated term for loss or damage to specified property by fire. See also separate article **FIRE INSURANCE**.
- First Class Mail Insurance.**—Designed to provide all risks coverage for banks, bankers, trust companies, insurance companies, security brokers, investment firms, investment corporations, stock clearing corporations and corporations when acting as security transfer agents or registrars for their own security issues. Shipments of bonds, coupons, stock certificates and other securities by first class mail and first class air mail are covered between places in the continental United States, excluding Alaska.
- Floater Policy, or Floater.**—Covers mobile property not easily insured by specific forms because it changes value or location; in ocean marine insurance, covers cargo on any ships of approved lines.
- Forfeiture Bond.**—Type of bond that grants to obligee right to demand payment of full penalty for any infraction of bond conditions.
- Forgery Bond.**—Indemnifies for loss through forgery or alteration of negotiable instruments. There are many forms, as for depositors, financial institutions, and securities houses.
- Fraternal Insurance.**—A class of life insurance providing mutual protection, on the cooperative plan, to their members by noncapital stock societies. Such societies aim also to engender fellowship and benevolent helpfulness through activities of a lodge system.
- Freights Insurance.**—Covers freight as cargo, if at risk of cargo owners; covers voyage freight or charter hire for account of vessel owner.
- Fur Floater.**—Indemnifies individuals for loss or damage to furs and fur garments in any location arising from all risks with specified exclusions.
- Furrier's Customers' Floater.**—Provides coverage for furrier against loss or damage to fur or fur-trimmed garments left for storage, alteration or repair.
- Garage Liability Insurance.**—Covers legal liability of garage owner arising from ownership, maintenance, or use of any automobile in insured's premises, and such liability arising from ownership, maintenance, occupation, or use of the insured premises.
- Garment Contractor's Floater.**—Provides coverage for manufacturer of clothing against named perils on premises of his contractors and their subcontractors, and against transit risks.
- General Average.**—In ocean marine insurance, a loss caused or extraordinary expense incurred by voluntary and successful act to avert common peril, requiring contribution by all insureds to indemnify interests affected by such loss or extraordinary expense.
- General Average Bond.**—Guarantees that owner of goods subject to general average will pay his proportionate contribution when ascertained; it is given to obtain immediate release of such goods.
- Glass Insurance.**—Indemnifies for loss through breakage from any cause except fire, and for damage through acids or chemicals, to various kinds of glass, including lettering and frames.
- Group Annuity Policy.**—Provides income to employees for life after retirement age.
- Group Insurance.**—See separate article **GROUP INSURANCE**.
- Hangar Keepers' Liability Coverage.**—Special form of aircraft liability insurance, providing coverage for owners or operators of aircraft hangars.
- Health Insurance.**—Indemnifies for loss of time from occupation through sickness, and for hospital, nurse, and surgical expenses, and in one form also for medical expense; written only in combination with accident insurance. See also separate article **HEALTH INSURANCE**.
- Hospitalization Insurance.**—Indemnifies for hospital and related charges incurred through accident or disease.
- Hull Insurance.**—See terms *Vessels, Hull Insurance; Aircraft Hull Insurance*.
- Identification Indemnity Provision.**—In accident insurance policy, undertakes to pay expense of notifying insured's relatives and putting him in their care, with limit usually of \$100, if by reason of injury he is unable to communicate with them.
- Indemnity Bond to Sheriff.**—Type of court bond protecting sheriff against loss for wrongful attachment or sale of property.
- Industrial Life Insurance.**—Provides coverage similar to that of ordinary life insurance but not in so many forms and usually with earlier age of maturity; the amounts of insurance, determined by the age of the insured at the time of issuance of policy and by the amount of his premiums, are small, averaging less than \$300, and the premiums are payable weekly or monthly.
- Inland Marine Insurance.**—A class of insurance embracing those forms that indemnify for loss or damage through sundry perils to various kinds of mobile property in transit.
- Installment Floater.**—Provides coverage for vendor, or vendor and vendee, against loss through transportation and fire hazards to property purchased by installments when title remains in vendor. This coverage may be extended also to other hazards.
- Installments for Life Option.**—Provides that upon the maturity of a life insurance policy a stated amount will be paid monthly, quarterly, semiannually, or annually for the life of beneficiary, or for a specified period to beneficiary and other specified persons.
- Insurable Interest.**—Exists when beneficiary has reason to desire continuance of life of insured person or property and would suffer economic loss by death or destruction of, or injury or damage to, such subject matter.
- Interest Option.**—Provides that interest at stated rate on amount due on life insurance policy at maturity will be paid monthly, quarterly, semiannually, or annually to beneficiary. The principal sum by agreement is withdrawable or payable to other specified persons on the happening of a specified contingency.
- Internal Revenue Bond.**—Guarantees payment of taxes and compliance with regulations on certain products within the United States, as alcohol, spirits, beer, wine, gasoline, tobacco.
- Joint Life Insurance.**—A form of life insurance which is payable upon the first death of those named as the insured; it is written with various terms to meet individual needs and may be made payable to the survivor or survivors or to a third-party beneficiary. See also

- separate article **LIFE INSURANCE**.
- Judicial Bond**.—See term **Court or Judicial Bond**.
- Leasehold Interest Insurance**.—Provides coverage for holder of long lease if, when cancelled by lessor on happening of a peril, as fire, its rental is less than current rentals.
- Liability Floater**.—Covers legal liability of carrier to shipper or consignee for loss or damage to property transported.
- Liability Insurance**.—A class of insurance embracing those forms that cover legal liability of insured to others for bodily injury, death, or property damage; called also third-party insurance. See also separate article **LIABILITY INSURANCE**.
- License Bond**.—Guarantees compliance with law and regulations by persons engaged in certain enterprises that affect the public interest, as electricians, milk dealers, auctioneers, and amusement park operators.
- Life Insurance**.—See terms **Ordinary Life Insurance**; **Industrial Life Insurance**; also separate article **LIFE INSURANCE**.
- Limited Installment Option**.—Provides that amount due on life insurance policy at maturity with interest will be paid monthly, quarterly, semiannually, or annually to beneficiary for a specified period or in specified amounts till the total is exhausted.
- Limited Payment Life Insurance**.—Provides coverage similar to that of ordinary life insurance, but premiums are due for specified period only, as for 10, 20, or 30 years.
- Loss**.—In insurance, the amount of diminution or destruction of the values of, or the amount of the charge upon, the insured by the direct consequence of the operation of the risk covered, according to the values specified in the policy; it constitutes a basis for a claim against the insurer.
- Lost Instrument Bond**.—Protects issuer of duplicate lost valuable paper against loss through reappearance of original.
- Manufacturers' Public Liability Insurance**.—Covers legal liability of insured for bodily injury or death arising from his business operations, including installing and servicing off premises.
- Marine Liability Insurance**.—Covers legal liability of insured to third parties for loss, damage, or expense arising from ownership, use, maintenance, repair or construction of any craft or instrumentality in use in ocean transportation, including liability for bodily injury, illness, or death.
- Medical Payments—General Liability**.—Provides for the payment of all reasonable expenses incurred within one year from the date of accident for necessary medical, surgical, dental, ambulance, hospital, professional nursing and funeral services to or for each person who sustains injury, caused by accident, and arising out of the insured's ownership, maintenance or use of premises, or his operations.
- Money and Securities Policies**.—One form, *premises all risks* policy, provides coverage against loss of money and securities on premises caused by destruction, disappearance, or wrongful abstraction thereof, and damages to premises caused by robbery or burglary; another form, *messenger all risks* policy, provides coverage against loss of money and securities outside premises in transit by custodian, caused by destruction, disappearance, or wrongful abstraction thereof. Both forms exclude losses caused by dishonest employees, voluntary surrender of the property, or forgery.
- Name Schedule Bond**.—A fidelity bond covering employees listed, each for a fixed amount.
- National Service Life Insurance**.—Offered by the federal government with special provisions as to amounts of protection and terms of payment to men and women in the armed forces during wartime, the extra hazard of military service being assumed as a national risk.
- Nationwide Definition and Interpretation of the Insuring Powers of Marine and Transportation Underwriters**.—Statement approved by National Association of Insurance Commissioners, 1913, revised 1953, to clarify in certain respects the state insurance laws with reference to overlapping insuring powers of insurers, and to coverages involving misapprehension among fire, marine, and casualty insurers. It enumerates (1) conditions under which marine and/or transportation policies may cover imports, exports, domestic shipments, and personal property floater risks; and (2) conditions under which such policies shall not cover property.
- Nonconcurrency**.—Arises when terms of policies are not alike as to items covered, interests insured, or distribution clauses.
- Nonforfeiture Provisions**.—State benefits available to life insurance policyholders upon lapse of policy for nonpayment of premium; they are (1) cash surrender value, (2) paid-up insurance, and (3) extended term insurance. The third usually is automatically operative unless holder selects one of the other two.
- Ocean Marine Insurance**.—Covers vessels, cargoes and freights chiefly against sea perils (sinking, stranding, and collision), and incidental shore and inland risks.
- Old Age Insurance**.—A class of insurance embracing those forms—individual, group, or social—designed to provide financial security for aged persons. See also separate article **PENSION OR RETIREMENT SYSTEM**.
- Open Policy**.—One in which the value of the subject matter insured has not been fixed but has been left to be determined in case of loss, or one in which the risk or subject matter insured is not fixed but is covered by insurer as reported by insured.
- Optional Settlements**.—Ways in which a life insurance policyholder or his beneficiary may elect to have applied the amount payable on the policy at maturity in lieu of one immediate cash payment; they are (1) interest option, (2) limited installment option, and (3) installments for life option.
- Outage Insurance**.—By endorsement on boiler and machinery insurance policy, indemnifies for increased cost of maintaining business without the damaged object.
- Overinsurance**.—Exists when insurance is written in an amount larger than is justified by the risk. It may occur, for example, in life, fire, or accident and health insurance.
- Owners' Landlords', and Tenants' Public Liability Insurance**.—Covers legal liability for bodily injury or death arising from ownership, maintenance, occupation, or use of insured premises.
- Owners' and Contractors' Protective Liability Insurance**.—Covers legal liability of owner or general contractor for bodily injury or death through acts respectively of his contractor or subcontractor.
- Owners' Protective Contract Bond**.—Guarantees owner that construction contract will be performed faithfully and that labor and material-men will be paid.
- Paid-Up Insurance**.—Amount of coverage available to life insurance policyholder upon and after he cancels his policy or permits it to lapse, without further premium payments; it is an optional nonforfeiture value and may not be less than the cash surrender value.
- Parcel Post Insurance**.—Indemnifies shipper for loss through all risks of package, insured or uninsured, registered or unregistered, in custody of Post Office Department till arrival at addressee's premises. There is a reporting form for monthly reports by larger shippers, and a coupon form, 100 to 1,000 coupons, for smaller shippers.
- Partial Disability**.—In accident insurance, injury that prevents insured from performing one or more important duties of his occupation.
- Participating Insurance**.—Refunds to insureds a portion of premiums, representing earnings by insuring company through excess interest received on investments, favorable mortality experience and savings in expenses. In nonparticipating insurance such earnings are anticipated in the premium rates, and company profits benefit the stockholders.
- Particular Average**.—In ocean marine insurance, loss of, or damage to, a particular interest (ship, cargo or freight) which is not general average.
- Partnership Insurance**.—May be written (1) insuring each partner for the amount of his capital, which is thus safeguarded for the use of the firm upon the death of the insured; or (2) insuring the partners in a joint life policy wherein upon the first death the amount is payable to the survivors and the insurance expires.
- Pension Trust**.—Provides income to employees for life after retirement age, premiums being contributed by employer and/or employees; separate policies usually are issued, though blanket policies also are written. See also separate article **PENSION OR RETIREMENT SYSTEM**.
- Permit Bond**.—Guarantees compliance with law and regulations by persons operating on or under public property or in the air.
- Personal Effects Floater**.—Provides coverage for insured and family against all risks, with exceptions, of loss or damage to personal effects, as those of a tourist, with exclusions, in any location.
- Personal Jewelry-Fur Floater**.—Provides coverage for insured and family against all risks, with exceptions, of loss or damage to scheduled jewelry and furs in any location.
- Personal Liability Insurance**.—See term **Comprehensive Personal Liability Policy**.
- Personal Property Floater**.—Covers all personal property, with specified exceptions, of insured and family, wherever located, against all risks of loss or damage, with exclusions in certain cases.
- Power Interruption Insurance**.—Indemnifies for consequential loss or spoilage arising from accident in public utility equipment causing interruption of service.
- Primary Commercial Blanket Bond**.—A fidelity bond providing coverage similar to that of blanket position bond, but differing in that it specifies amount available for any single loss rather than separate amounts for each employee.

- Principal Sum.**—Amount or portion thereof payable in accident insurance policy upon death or specified disability caused by accident.
- Pro Rata Premium.**—Charged when insurer cancels policy, or when insured cancels one policy and takes another with same insurer.
- Probate Bond.**—See term *Fiduciary or Probate Bond*.
- Processing Floater.**—Provides coverage for processor of goods, as cotton, silk and wool, against named perils on premises, and transit risks.
- Products Public Liability Insurance.**—Covers legal liability of insured for bodily injury or death through use, consumption, or existence of his product after he relinquishes it.
- Professional Liability Insurance.**—Covers legal liability of persons, as physicians, surgeons, dentists, and druggists, for bodily injury or death caused by malpractice, errors or mistakes of insured or his nurses or clerks.
- Profits and Commissions Insurance.**—Indemnifies manufacturer or middleman for loss of earned profits or commissions through damage to finished goods resulting from named peril.
- Prospective Restoration Clause.**—After discovery of loss on fidelity bond, restores face amount for losses subsequently occurring.
- Public Liability Insurance.**—A class of insurance embracing those forms that cover legal liability for bodily injury, death or property damage, except liability arising from maintenance, operation or use of automobiles. The common forms are: manufacturers' and contractors' liability; owners', landlords', and tenants' liability; elevator liability; owners' and contractors' protective liability; products liability; and contractual liability.
- Public Official Bond.**—For federal, state and local governments, guarantees faithful performance of official duties by public officials, and safekeeping and accounting of public funds. The form of bond usually is fixed by law.
- Reinstatement.**—Refers to reinstatement of policy amount after loss, or in life insurance to reinstatement of policy after lapsation.
- Reinsurance.**—A contract by which an insurance company procures a third party, commonly an insurance company, to insure it against loss or liability by reason of a policy it has written.
- Rent, Rental Value Insurance.**—Indemnifies owner-occupant when forced to evacuate premises as a result of fire for cost of rent in other premises during period of rehabilitation, or landlord for loss of normal rental income during enforced evacuation of tenants from a similar cause.
- Replacement Cost Insurance.**—Insurance covering on building may be extended by endorsement to cover the difference between the actual cash value and the actual cost of repair or replacement without deduction for depreciation.
- Reporting Form or Policy.**—Covers fluctuating properties or risks, premium being based on periodic reports by insured.
- Representation.**—As applied to insurance, distinguished from warranty. See term *Warranty*.
- Reserve.**—In life insurance, portion of premium set aside and invested by insuring company to build up fund to meet future death claims.
- Residence, Farm Liability Insurance.**—A division of owners', landlords' and tenants' public liability insurance, includes garages and outbuildings, and injuries from pets on premises. Coverage for acts of dog off premises may be added by endorsement.
- Residence and Outside Theft Insurance.**—Indemnifies insured and entire family including guests and servants within premises for loss of property caused by burglary, robbery, theft, or larceny. Outside coverage without charge (except in New York City counties of Bronx, Kings, New York, and Queens) also is included except on guests.
- Retroactive Restoration Clause.**—After discovery of loss on fidelity bond, restores face amount for losses subsequently discovered.
- Reversionary Interest.**—Refers to benefits payable to a named beneficiary upon death of insured; while this term has general and wide application, specific policies, such as reversionary annuities, and deferred survivorship annuities, otherwise known as continuous installment policies, provide for payment of income benefits to a named beneficiary at death of the insured.
- Rider.**—A printed agreement attached to an insurance policy.
- Scheduled Property Floater.**—Provides coverage against loss or damage to a variety of named items of mobile property in any location, arising from specified or all risks.
- Securities Insurance Policy (for Lessees of Safe Deposit Boxes).**—Provides coverage against loss caused by destruction, disappearance, or wrongful removal of securities in, or from, leased safe deposit boxes. It excludes losses caused by dishonest employees or authorized representatives of the insured, or by voluntary surrender of the property by them or by the insured.
- Securities Policy.**—Provides coverage for financial institutions and brokerage houses against specified losses caused by defective securities. This coverage commonly is incorporated in bankers' and brokers' blanket bonds.
- Settlement Options.**—See term *Optional Settlements*.
- Short Rate Premium.**—Charged for less than one year, or when policy is cancelled by insured without reinsuring in same insurer.
- Single Premium Life Insurance.**—Provides coverage similar to that of ordinary life insurance, with total premium obligation paid in one amount.
- Social Insurance.**—A general class of insurance embracing those forms designed to protect wage earners and their dependents, as workmen's compensation, old age, unemployment, accident and health insurance.
- Specific Policy or Form.**—Covers at a specific location against hazards insured.
- Sports Liability Insurance.**—Covers legal liability of insured for bodily injury or death arising from his activity in athletic sport or game, except professional activity.
- Superseded Suretyship Rider.**—Endorsement on new fidelity bond, providing continuous coverage with replaced bond.
- Supplemental Contract or Deposit Receipt.**—Is in effect a receipt issued by a life insurance company to a claimant under a life insurance policy for funds held for the claimant's benefit under settlement options, (1) interest, (2) life annuity, 10, 15, or 20 years certain, (3) payment of principal and interest over a specified period of years, or (4) a specified income for as long as the proceeds will last.
- Supply Bond.**—Guarantees that supplier of goods will perform terms of his contract.
- Suretyship.**—An undertaking by one party (the *surety*) guaranteeing performance by another party (the *principal*) of an obligation with a third party (the *obligee*).
- Surrender Value.**—See term *Cash Surrender Value*.
- Teachers' Liability Insurance.**—Covers legal liability of teachers and faculty members for bodily injury or death arising from personal acts in connection with their profession.
- Term Insurance.**—Provides coverage for a specified period, the policy amount being payable if insured dies during the period.
- Third-Party Insurance.**—See term *Liability Insurance*.
- Time Policy.**—In ocean marine insurance, provides coverage for vessel or cargo or both for a specified period of time.
- Title Insurance.**—See separate article *TITLE INSURANCE*.
- Tontine Policy.**—Provides that at the end of a specified period the surplus fund shall be distributed among those in their class who have kept their policies in force, the lapsing members of each class forfeiting their rights and receiving nothing and the reserve values of their lapsed policies being credited to the surplus fund.
- Total Disability.**—In accident insurance, injury that prevents insured from performing any and every duty of his occupation.
- Total Loss.**—In ocean marine insurance, a total loss occurs when the subject matter is entirely destroyed or so damaged that it is of no use or value to the insured, or when the insured is deprived entirely of his property; see term *Constructive Total Loss*. In fire insurance, a total loss occurs when the subject matter loses the essential character of the property insured; complete physical destruction usually is not required by the term, provided the remaining portion, though unburned, cannot profitably be utilized.
- Transportation Insurance.**—A general class of insurance embracing those forms that indemnify for losses arising from transportation risks. In inland marine insurance, it is the basic form of in-transit coverage with many optional endorsements or riders for specific coverages.
- Underwriter.**—See separate article *UNDERWRITER*.
- Unearned Premium Endorsement.**—Indemnifies for loss of portion of paid premium caused by reduction of policy amount through loss.
- Unemployment Insurance.**—A class of insurance embracing those forms designed to provide relief for wage earners and their dependents during periods of unemployment.
- Unknown Hazards.**—A hazard within the scope of the coverage but the existence of which with respect to the individual risk is unknown.
- Use and Occupancy Insurance.**—See term *Business Interruption Insurance*.
- Valued Policy.**—States within the instrument itself the amount to be paid in case of loss, thus avoiding determination of such amount after loss by appraisal or adjustment.

- Vessels, Hull Insurance.**—Covers ocean-going vessels, yachts, barges, and tugs on annual basis or for specific voyages.
- Voluntary Workmen's Compensation.**—Standard workmen's compensation policy may be endorsed to cover bodily injury or death of employees whose duties do not come within scope of any workmen's compensation law. When so endorsed policy provides for voluntary payment on behalf of insured employer of same benefits to or for such employees as would have been paid if injury or death had been sustained in an employment included in such law.
- Voyage Policy.**—In ocean marine insurance, provides coverage for vessel or cargo or both from one designated port to another; more than one voyage may be covered in one policy.
- Wager Policy.**—In insurance, one in which the insured has no insurable interest in the subject matter insured; being considered generally as a form of gambling, such a policy is not valid except where the validity of a wager may be recognized. In ocean marine insurance, agreements, often called "honor agreements," may be written where the interest of the insured is difficult or impossible to prove.
- Warehouse Bond.**—Guarantees validity of receipt given for property by warehouseman, or payment of duty and taxes, and compliance with regulations, on property received by warehouseman.
- Warranty.**—As applied to insurance, a statement or engagement by insured which if not true or fulfilled voids the insurance contract. It is distinguished from a representation, which is an inducement and need be only substantially true or fulfilled.
- Workmen's Compensation Insurance.**—See separate article **COMPULSORY INSURANCE**; **SOCIAL SECURITY—Workmen's Compensation**.

INSURRECTION, in-sŭ-rĕk'shŭn, the art of rising against political authorities. In the United States, power to suppress insurrections by employing the militia is given to Congress by the

Constitution, Article I, section 8, clause 15. In 1792 and 1807 acts were passed giving the president power to call forth the militia when notified by an associate justice of the Supreme Court or a district judge that the execution of the laws is obstructed, and on application of a legislature or a governor, when the legislature could not be convened, and to employ also the land and naval forces of the United States. The Whiskey Rebellion was directed against the federal authority and the president employed force to suppress it on notification by the federal judge. During the Buckshot War (q.v.), in 1838, between the Whigs and Democrats in Pennsylvania, the governor of that state asked for assistance, but it was refused. The governor of Rhode Island made a similar application during Dorr's Rebellion (q.v.) and the regulars were held ready for action, but their aid proved unnecessary. These last two cases came under Article IV, section 4, of the federal Constitution, which provides "that the United States shall protect" each state on application of the legislature, or of the executive, against domestic violence.

When the Civil War began the president was obliged to take prompt steps in calling out the militia, though no application had been made to him as required by the acts of 1792 and 1795. His action was justified by Article II, section 3, of the Constitution, providing that "he shall take care that the laws be faithfully executed," but Congress on Aug. 6, 1861, formally validated and made legal all of President Lincoln's previous acts, proclamations and orders. The Force Act of April 20, 1871, gave the president special power to use military force in certain contingencies. In the South during the reconstruction period, and in the North during strike riots, federal troops have been used.

INTAGLIO, in-tă'l'yō, a method of cutting a stone or gem by which the design is cut or hollowed out—not raised, as in a cameo. In art, the term means the opposite of relief, denoting the representation of a subject by hollowing out a gem or other substance, so that an impression from the engraving has the appearance of a bas-relief. Intaglio letters have been effectively used in printing in recent years, and much of the effectiveness of colored printing is due in large measure to a process or processes closely akin to intaglio. See also **GRAPHIC ARTS—Glossary of Graphic Arts Terms** (Intaglio), (Rotogravure).

INTEGRAL CALCULUS. See **CALCULUS**—5. *The Indefinite Integral*; 6. *The Definite Integral*.

INTEGRAL EQUATIONS. See **EQUATIONS**—4. *Integral Equations*.

INTEGRATION. See **SEGREGATION IN THE UNITED STATES**.

INTELLECT. See **INTELLIGENCE**.

INTELLECTUALISM, in philosophy, theories which emphasize the intellect as contrasted with the affective and volitional aspects of consciousness. In philosophy it applies, for example, to Johann Friedrich Herbart's doctrine of presentations, in which cognitive experiences are made primary in the explanation of mind. The historical antithesis between sensation and

intellect gives the term intellectualism to theories which find the ultimate nature of reality in some form of thought or reason. By some reality is reduced to intellectual relations. In aesthetics the view of intellectualism regards the ideas suggested by an object as the important factors in beauty. Recent philosophic thought, however, is departing from the crass intellectualism of even a few years ago. Henri Bergson is the greatest figure who has opposed intellectualism in our day.

INTELLIGENCE, ĭn-tĕl'ĭ-jĕns, the ability to make effective use of past experiences in adjusting to new situations. In traditional mental philosophy intelligence was defined as a trait uniquely human, and the behavior of animals was thought to be directed by instincts. Human beings, therefore, were thought to be able to master the environment through the exercise of the faculty of intelligence.

Teachers have always recognized the fact that some pupils learn with ease and that others have serious handicaps in ability to master the curriculum. The first successful measure of differences in ability to learn was used in 1904 by Alfred Binet (q.v.) and Theodore Simon in an inquiry into the problem of retardation in French elementary schools. Their novel technique attracted worldwide attention. The famous Binet-Simon Scale was published in 1905 and revised in 1908 and 1911 to incorporate suggestions made by psychologists here and abroad.

Among those who adapted the procedure for use in studies of American school children was Lewis Madison Terman (1877-1956). His test, published in 1916 and revised in 1937, became the most widely used measure of intelligence in America. Whereas Binet was not concerned with a definition of intelligence, Terman wrote that it is the ability to make use of abstract concepts. This definition aroused much discussion. Many other definitions were proposed, but none of them was wholly acceptable to educators and psychologists.

Following World War I, psychologists commenced to write about a number of specific abilities rather than of a single trait labeled intelligence. It was noted that the conventional measures of intelligence seemed to appraise the level of ability to learn the school curriculum, especially the conventional academic studies. Measures of performance in dealing with form-boards, puzzles, and mechanical devices yielded scores that were sometimes different from those obtained from verbal tests. It was also noted that a person might do fairly well on both verbal and nonverbal tests of intelligence, but make a low score on a measure of social intelligence. Hence, three different types of intelligences were more or less vaguely defined: verbal, mechanical or nonverbal, and social.

Research centered upon the analysis of intelligence-test scores and their relationship to sex, race, environment, family background, teachers' marks, and afterschool life-careers. Impetus to the use of group tests of intelligence was given by the measures used in the United States Army during World War I. Debates about an unambiguous definition of intelligence were of less interest than efforts to accumulate scores on intelligence tests and to interpret the meanings of these data.

Binet had worked out a technique for evaluating a person's intelligence by comparing his level of success on test items with that achieved

by the average individual of a known chronological age. Thus, if a child passed all the tests passed by the average child six years of age, his mental age (M.A.) would be six, regardless of his chronological age (C.A.). Louis William Stern (1871-1938) suggested that intelligence-test results might be expressed in terms of a ratio between mental age and chronological age. Terman popularized this method. The scores are converted into I.Q.'s by the formula: M.A./C.A. times 100. Thus, an I.Q. of 80 represents a deficit, and an I.Q. of 120 an excess, of intelligence.

In recent years psychologists have shifted their interests from attempts to measure intelligence, loosely defined as a single trait, over to diagnostic tests of specific abilities. Both here and abroad there has been developed a set of techniques for measuring what are often referred to as primary mental abilities. Scores on these tests have proved to be helpful in the selection of personnel for industry and military assignments as well as in educational guidance.

A plurality of abilities, not a single trait labeled general intelligence, seems to be of importance in predicting a person's likelihood for success or failure in any given field of endeavor. Among the primary mental abilities that now receive attention are the following: verbal comprehension, rote memory, word fluency, number facility, ability to visualize spatial relations, and perceptual speed and accuracy. These patterns of intelligences have been carefully studied by Louis Leon Thurstone (1887-1956), of the University of Chicago.

It is obvious that intelligence is a difficult term to define. It may very well be plural, not singular, in meaning. The interest continues in the development of predictive scales and tests for the appraisal of abilities. Enthusiasms for theoretical discussions about the nature of intelligence, or intelligences, have greatly diminished both in this country and abroad. Recent investigations have raised grave questions about the traditional dogmas. For instance, it was once assumed by many persons that heredity is the principal determinant of the IQ and that native intelligence reaches its maximum at about age 15 or 16. Considerable doubt has been raised about these inferences and also about the constancy of the IQ as well. For intelligence in animals see **ANIMAL PSYCHOLOGY**; also **EDUCATIONAL PSYCHOLOGY**; **MENTAL TESTS**.

INTERCALARY, ĭn-tŭr'kă-lĕr-ĭ, in chronology, the day added to February in leap year, also the month or days occasionally inserted in the calendar to make it correspond with the solar

year. See also CALENDAR.

INTERCESSION, Doctrine of, a theological tenet founded on the Scriptural representation of Christ who, having made the redemption an accomplished fact on earth, ascended to plead with His heavenly Father for the sinners redeemed by the shedding of His blood. We are not to suppose that God needs to be interceded with in the sense that he is reluctant to pardon sinners, or that he becomes more disposed to do so through the pleading of Christ. Since it is evident from the whole tenor of the New Testament, as well as from a multitude of special passages, that the sacrifice of Christ on Calvary for the reconciling of sinners unto God was itself the offering of God's own love to the world (John 3:16-17), we must regard the intercessory work of Christ rather as illustrating the eternal holiness of God and the changeless love of the Saviour, and as intended to keep continually in view the sacrifice of atoning grace whose tender mercy it develops. This doctrine is common alike to Catholics and Protestants. Catholics, however, believe that the Blessed Virgin and the saints intercede indirectly through the Saviour, who alone has the ear of the King of the universe. Mohammed is regarded as a powerful intercessor by his followers.

INTERCOASTAL WATERWAY OR INTRACOASTAL WATERWAY, and GULF INTRACOASTAL WATERWAY. The first is a protected waterway comprising interconnected canals, bays, inlets, and rivers extending 1,000 miles along the Atlantic coast of the United States. From Trenton, N.J., to Melbourne, Fla., the channel has a 12-foot draught; thence to Miami, 8-foot, and from Miami to Key West, 4-foot. The Gulf Intracoastal Waterway provides a navigable channel with 12-foot depth from Carrabelle, Fla., to Brownsville, Texas, also about 1,000 miles.

INTERCOLUMNIATION, in-tēr-kō-lŭm-nŭ-ā'shŭn, in architecture either (1) the space between two adjacent shafts of a colonnade, or (2) the ratio of the greatest diameter of the shaft to the distance between shafts at the base or (sometimes) between the centers of the shafts.

Marcus Vitruvius Pollio enumerated five varieties of intercolumniation, according to the number of times the bottom diameter of the shaft appeared between the nearest points of adjacent columns. Thus (1) pycnostyle employs $1\frac{1}{2}$ diameters; systyle 2 diameters; eustyle $2\frac{1}{4}$ diameters; diastyle 3 diameters; and areostyle 4 diameters. Claude Perrault (1613-1688) on the Louvre, and repeated by Christopher Wren (1632-1723) on St. Paul's Cathedral is known as areostyle, wherein columns are paired, with $\frac{1}{2}$ diameter between member shafts and $3\frac{1}{2}$ between pairs.

Intercolumniation in the Ionic and Corinthian styles is usually greater than in Doric, where the distance between nearest parts of shafts was sometimes less than one diameter.

To the later ancients the eustyle ($2\frac{1}{4}$ diameters) was the most satisfactory proportion. Vitruvius held that the minimum absolute space between columns should be such as to allow the passage of two matrons arm in arm.

JOHN P. SEDGWICK.

INTERDICT, in-tēr-dĭkt, an ecclesiastical decree which forbids the performance of certain

acts of public worship. When an interdict was laid upon a town, district or country, all the churches were closed, the bells were silent, the sacraments, except infant baptism and extreme unction (and sometimes even these), were withheld, the rites of burial were not performed and all the public ceremonies of religion were suspended. Interdicts may be general, as applied to a country or city; particular, as applied to a parish or diocese; personal, as applied to a person, or some class of persons. In 997 Gregory V laid the kingdom of France under an interdict because King Robert had married his cousin, and the king was abandoned by most of his court. The same penalty was inflicted upon the kingdom of England under Stephen (1147) by Eugenius III, under John (1207) by Innocent III, under Henry VIII (1535) with little effect by Paul III and under Elizabeth (1587) by Sixtus V. Adrian IV laid Rome under an interdict for the purpose of compelling the Romans to drive out Arnold of Brescia. Gregory IX made use of the same instrument of compulsion in his quarrel with the Emperor Frederic II. During the Middle Ages the interdict was a powerful engine of attack for the popes in their contests with sovereigns, as the popular dread of its effects was so great that kings were often forced by rebellions to submit to almost any conditions in order that it might be taken off. From the time of the Reformation general and local interdicts have become rare. When Paul V laid Venice under an interdict in 1606, the churches were not closed, and only a minority of the bishops submitted to it.

INTERDICT, in Scottish law, an order issued by the Court of Session to stay or prohibit a person from an act presumed to be illegal or wrongful. It is similar to the injunction in English and American procedure. See also INJUNCTION.

INTEREST, in-tēr-ĕst, a charge for the use of money. It is usually expressed as a percentage of the amount loaned, and is computed on an annual basis. Interest is charged by those who have money to lend because they give up its use for a specified period of time. Interest can be paid because the borrower anticipates a greater return, in income or other benefits, than he contracts to pay.

Interest has not always been considered a legitimate, or even moral, payment. Until the end of the Middle Ages, any charge for a loan was generally considered to be usury. The teachings of the Christian, Judaic, and Islamic religions all condemned in varying degrees the taking of interest. In more recent times, however, usury has come to be regarded as only the charging of illegal rates of interest (see USURY). The taking of interest for a loan is now almost universally regarded as a legitimate aspect of economic activity.

The shift in attitude toward the payment of interest stemmed from a change in the economic pattern of Western society in particular. This led to an altered view of the nature and function of money. The Aristotelian and Biblical views held that "money is barren." That is to say, money was regarded as only a medium of exchange. The loan of money was considered to be in the nature of a sale. As it was not legitimate to sell a loaf of bread to a man and then charge him for the use of it, so it was not legitimate to

sell money and also charge for its use. The proper price, according to doctrine through the Middle Ages, was simply the return of the same money. Any greater payment was termed immoral, and called usury.

The development of commerce on a widespread basis led to a gradual breakdown of the interdictions against interest. As increased industry and commerce afforded greater opportunities for profit, loans were more actively sought. Traders, merchants, and businessmen were willing to pay interest because they anticipated a greater return from the employment of the borrowed funds. Thus, as the practice of borrowing and lending at interest became more widespread, there arose a number of exceptions or modifications which in fact tended to break down the prohibition of usury or interest-taking. In theory, however, these modifications were merely variations necessary for the fuller attainment of the idea of justice.

Since interest is a price—the price for the use of money—it is determined by the forces of supply and demand. Explanations or theories of the origination of interest must therefore state clearly why interest must be paid and how interest can be paid. In the development of interest rate theory, the latter approach was emphasized first historically, and by many years.

The first formal, theoretical justification of interest was a demonstration that the use of money could be productive of income. Although fragmentary indications were prevalent in earlier writings, the productivity approach to interest theory really developed with Adam Smith (1723–1790). Despite many variations, the basic thesis is that money will be borrowed, and interest paid, so long as the return that can be earned on the borrowed funds exceeds the interest rate. Interest was therefore paid because income could be derived from the use of money.

The supply side of interest rate theory was first treated systematically by Eugen Böhm-Bawerk in the 1880's. His was a time-preference, or abstinence, theory. According to it, the worth of a sum of money presently held is greater than the worth of that same sum payable at some time in the future. The preference of the lender for money to use now over money promised in the future causes him to require some premium.

Modern economic analysis has added variations to these basic approaches. John Maynard Keynes (1883–1946) has argued that interest stems directly from the supply of and demand for money itself, rather than the use of money. His theme is that liquidity is the unique characteristic of money, and he calls the demand for money to hold "liquidity preference." It is this which requires the payment of interest.

More recently, the loanable funds approach has combined the three basic approaches outlined above. It considers interest as a function of supply and demand for loanable funds, which are that portion of the money supply available for lending purposes. The elements of both supply and demand, as well as the influence of liquidity preference, are brought together in this approach.

The interest rate discussed here is the pure, riskless payment for the use of money. Interest payments made in actual practice also include charges for risk and for reimbursement of administrative expense. Variations in risk and in lending cost lead to a whole range of interest rates called the pattern of rates. At the base of

each element in this pattern, however, is the pure, riskless rate of interest determined by productivity, time preference, and liquidity preference.

The payment of interest is a contractual matter. The concept of usury still prevails, however. Society has set limits on what may be considered legitimate compensation for lending money. Any payment beyond that is usury, which is illegal. The recipient of usurious interest may be subject to a fine, a suit for damages, or both, depending on the jurisdiction. In the United States, the several states have established contract and legal limits for interest rates, and in addition have established the penalties for violation of the usury laws.

INTERESTS AND THEIR MEASUREMENT. Interests are revealed in the specific choices one makes in various situations. A verbalized interest in some vocational field may reflect nothing more than acceptance of some popular stereotype derived from motion pictures. Paucity of information about the specific choices made by successful persons in various occupational fields may mislead a person who is trying to select a career. For such reasons, a group of psychologists at the Carnegie Institute of Technology began to study the possibility of measuring patterns of interest among successful men and women in a number of vocational fields. This work, initiated in 1919, was continued by Edward K. Strong, Jr.; and it led to the development of a paper-and-pencil inventory known as the *Strong Vocational Interest Blank*, the first edition having been published in 1927.

More than 400 occupations, amusements, school subjects, types of persons, activities, and self-appraisals of traits are to be marked "like," "indifferent," "dislike." Each choice has a numerical value, determined from the scores of successful and well-adjusted persons in different occupational fields. Hence, it is possible for a student to determine whether or not this pattern of interests actually conforms to the pattern of those who are happy in their vocation. Since patterns of interests tend to remain fairly stable after age 20, the *Strong VIB* is often used in employment offices and in college guidance laboratories. Follow-up investigations, both by repetitions of the inventory and by later careers of those who have been tested, indicate that this measurement has satisfactory validity.

More than 30 other inventories of interests and preferences are available. Some of them are, like the *Strong VIB*, intended to be used in vocational guidance. Others have been devised for use with small children for research purposes. Children choose among pictures, objects, or activities. Thus, they reveal interests which might not be dependably verbalized if they were questioned directly. Psychologists are interested in patterns of interests among children of different types of home backgrounds, cultural opportunities, sex,

intelligence, and so on. In 1912 Edward Lee Thorndike reported that retrospective accounts of interest patterns reveal a rather high consistency from primary school through college years. He also observed that clergymen seem to have a growing interest in their calling, whereas in other fields of endeavor interest patterns tend to remain stable. Robert Hoppock, on the other hand, reported in 1935 that one-third of all employed persons are uninterested in their jobs.

Much attention has been paid to Eduard Spranger's discussion of value-interest types of personalities. In his *Lebensformen* (*Types of Men*, trans. 1928), Spranger takes the idealistic point of view that all men are admixtures of six value-interests, with one pattern tending to be more or less dominant. Intellectualistic pursuit of truth (the theoretical type); concern for the practical, the useful (economic type); interest in the artistic phases of life (aesthetic); love of human beings (social); leadership and power (political); and mysticism (religious type) are said to be the basic value-interests. For purposes of group discussion about the Spranger types, as well as for research studies of these patterns of value-interests, an inventory known as *Study of Values* (Boston 1951) has been published. Some evidence has been cited to indicate that the interest patterns, as Spranger has defined them, alter as life experiences vary.

PHILIP L. HARRIMAN.

INTERFERENCE, ĩn-tēr-fēr-ēns, the effect that trains of waves have upon one another when they meet. The waves may be water, sound, light, or electromagnetic. The effect may be either to increase or to decrease intensity, depending upon whether the crests and troughs of the waves coincide at the point of meeting or tend to neutralize one another.

The phenomenon may be observed when two different trains of waves come together on the surface of water. When the crest of a wave of one system coincides with the crest of a wave of the other system, the elevation of the surface is equal to the sum of the heights of both waves. When a crest of one wave coincides with the trough of another, surface disturbance is reduced and the elevation or depression is equal to the difference between the height and depth of the separate waves. The same rule governs when intermediate wave parts meet.

This phenomenon is of the same general sort with sound, light, and electromagnetic waves. When waves emanating from separate sources are of the same length and their crests and troughs reach a given point at the same time, they reinforce each other; when the difference in time is a half wave length, they cancel.

A familiar result, with sound waves of but slightly different lengths moving in nearly the same direction, is the production of "beats." With light waves, it can be observed on soap bubbles. Light striking a bubble is reflected toward the eye from both the inner and outer surfaces in trains of waves having slightly different phases. In monochromatic light, the effect appears as dark lines where the trains nearly or completely neutralize one another; in white light, the dark lines are replaced by bands of its various color components.

Interference is relied upon in the operation of radio beacons and the like for producing concentrated beams through the focusing of electro-

magnetic waves. Coming from two or more special antennas, the waves augment one another in the direction in which the crests and troughs coincide, and they are weakened or neutralized in the other directions.

In radio and television broadcasting, another type of interference occurs when stray electrical waves become mixed with the transmitted signals and reach the receiver as noise or as disfigurements of the image on the screen. They may be either from natural causes, such as lightning, or from electrical equipment.

In *mechanics*, the term is applied to certain gear designs, where the tip of a tooth of one gear tends to occupy the same space as the flank of the tooth of a mating gear, causing undercutting of the flank and rounding of the tip. It is overcome by modification of the tooth profiles. See also WAVES AND WAVE MOTION; LIGHT; ACOUSTICS; VIBRATION; RADIO; TELEVISION; GEARS.

INTERFEROMETER, ĩn-tēr-fēr-əm-ē-tēr, an instrument utilizing the interference patterns of light waves for precise measurements of wave lengths and of minute distances and thicknesses. It is also used in the study of the structure of spectrum lines, in determining indices of refraction, and in testing lenses, and has been employed in the measurement of double-star separations and the diameters of very large stars.

The best known was devised by the American physicist Albert A. Michelson (1852-1931). It consists of two mirrors that cause two light beams to come together at a point of interference between their waves. A micrometer screw on one of the mirror mounts provides for close adjustment. Another in use, the Fabry-Perot interferometer, utilizes multiple reflections between two surfaces, as does the less complicated but limited Lummer-Gehrcke plate. See also SPECTROSCOPY—*Spectroscopic Instruments*.

INTERGOVERNMENTAL COMMITTEE FOR EUROPEAN MIGRATION (ICEM), an international organization with headquarters in Geneva, Switzerland, which was created in Brussels in December 1951 at a conference called by the Belgian government at the suggestion of the United States. The ICEM was conceived as an instrument to restore the equilibrium between Europe's overcrowded countries, as Italy and the Netherlands, and undermanned countries in other continents through governmentally assisted migration. The persons assisted include political refugees. Though outside the framework of the United Nations, the ICEM maintains close working relationships with the U.N. and its specialized agencies dealing with migration. A policy-making council representing all 27 member governments normally meets twice a year. In 1957 the director of the ICEM was H. H. Tittmann of the United States.

INTERIM, ĩn-tē-rĭm, in the history of the Reformation, the name of several compromises forced on the German Protestants by edicts of Charles V, especially that of 1548, regulating religious and ecclesiastical matters "in the meantime," until they could be decided by a general council. The *Ratisbon Interim* was drawn up in 1541 by a commission which included Johann Eck, Martin Bucer, Julius von Pflug, John Gropper, Johannes Pistorius, and Melancthon (Philipp Schwarzerzt). Many doctrinal points

were smoothed over, but the differences in regard to the ecclesiastical power and the sacraments were too great to be reconciled. By the Protestants in general, the whole movement was looked on as a scheme to entrap them into a formal return to the Roman Catholic Church. In 1548 at Augsburg, the emperor appointed Johannes Agricola, Michael Helling, and von Pflug to prepare a new interim. This *Augsburg Interim* conceded to the Reformers communion in both kinds, and the marriage of priests. Great opposition developed in North Germany and the pact was revoked in 1552. Elector Maurice of Saxony secured the adoption of the *Leipzig Interim* in 1548, according to which the Protestant creed remained intact, with an admixture of the old ceremonial; the papal and episcopal powers were also recognized to a limited extent.

INTERIOR, Department of the. A major department of the executive branch of the United States government, the Department of the Interior was created by Act of Congress on March 3, 1849. The secretary of the interior is a member of the president's cabinet.

SECRETARIES OF THE INTERIOR

Name	Term of service	Presidents under whom served
Thomas Ewing	1849-1850	Taylor
James A. Pearce	1850	Fillmore
Thomas M.T. McKennan	1850	Fillmore
Alexander H.H. Stuart	1850-1853	Fillmore
Robert McClelland	1853-1857	Pierce
Jacob Thompson	1857-1861	Buchanan
Caleb B. Smith	1861-1863	Lincoln
John P. Usher	1863-1865	Lincoln,
		A. Johnson
James Harlan	1865-1866	A. Johnson
Orville H. Browning	1866-1869	A. Johnson
Jacob D. Cox	1869-1870	Grant
Columbus Delano	1870-1875	Grant
Zachariah Chandler	1875-1877	Grant
Carl Schurz	1877-1881	Hayes
Samuel J. Kirkwood	1881-1882	Garfield
Henry M. Teller	1882-1885	Arthur
Lucius Q.C. Lamar	1885-1888	Cleveland
William F. Vilas	1888-1889	Cleveland
John W. Noble	1889-1893	B. Harrison
Hoke Smith	1893-1896	Cleveland
David R. Francis	1896-1897	Cleveland
Cornelius N. Bliss	1897-1899	McKinley
Ethan A. Hitchcock	1899-1907	McKinley,
		T. Roosevelt
James R. Garfield	1907-1909	T. Roosevelt
Richard A. Ballinger	1909-1911	Taft
Walter L. Fisher	1911-1913	Taft
Franklin K. Lane	1913-1920	Wilson
John B. Payne	1920-1921	Wilson
Albert B. Fall	1921-1923	Harding
Hubert Work	1923-1928	Harding,
		Coolidge
Roy O. West	1928-1929	Coolidge
Ray Lyman Wilbur	1929-1933	Hoover
Harold L. Ickes	1933-1946	F.D. Roosevelt,
		Truman
Julius A. Krug	1946-1949	Truman
Oscar L. Chapman	1949-1953	Truman
Douglas McKay	1953-1956	Eisenhower
Fred A. Seaton	1956-1961	Eisenhower
Stewart L. Udall	1961-	Kennedy,
		L.B. Johnson

The duties and responsibilities of the secretary are shared by an undersecretary and five assistant secretaries. *The assistant secretary for water and power development* supervises the Bureau of Reclamation, Bonneville Power Administration, Southwestern Power Administration, Southeastern Power Administration, Office of Saline Water, and the Defense Electric Power Administration. *The assistant secretary for min-*

eral resources is responsible for the Bureau of Mines, Office of Geography, Office of Minerals and Solid Fuels, Office of Oil and Gas, Office of Minerals Exploration, Office of Coal Research, Oil Import Administration, and Geological Survey. *The assistant secretary for public land management* coordinates the functions of the Bureau of Land Management, Bureau of Indian Affairs, National Park Service, Office of Territories, The Alaska Railroad, and the Bureau of Outdoor Recreation. *The assistant secretary for fish and wildlife*—a post created in 1956 by act of Congress—is responsible for the Bureau of Sport Fisheries and Wildlife and the Bureau of Commercial Fisheries. *The administrative assistant secretary* supervises the divisions of administrative services, budget and finance, management research, personnel management, property management, security, and survey and review.

The department's chief responsibility is the conservation and development of the nation's land, water, and mineral resources. Originally, its two main branches were the General Land Office and the Office of Indian Affairs. Its major role in the 1800's was to develop the western areas of the United States. In its early years it also handled pensions and patents, and was responsible for taking the national census. Education, labor, and interstate commerce came under its jurisdiction at various times. It has been called the "mother of departments" because four government departments of cabinet rank—agriculture, commerce, labor, and (less directly) health, education, and welfare—evolved from the Department of the Interior.

As the nation's primary land agency, the department is directly responsible for managing almost 500 million acres of land in the United States and its territories. It also administers those areas of the Outer Continental Shelf that the Supreme Court may adjudge to be federal land. The department is responsible for mapping the physical features of the country; for protecting and preserving national parks, monuments, and historic sites; and for promoting the conservation and development of fish and wildlife resources.

The department conducts programs and helps industry carry out plans to explore and develop mineral resources to meet the nation's growing demands. It helps to assure adequate supplies of energy and to develop irrigation and multipurpose hydroelectric projects. It markets the electric power produced by all federal agencies except the Tennessee Valley Authority. In addition, it exercises certain mobilization functions related to national defense, chiefly for minerals, fuels, and electric power. The department is also responsible for the welfare of Alaskan Eskimos, widely scattered island populations, and more than 300,000 Indians.

INTERIOR DECORATION, the creative art which fulfills a basic urge to create beauty, comfort, and utility in the immediate environment, affording an opportunity for the decorator, as artist, to evoke—in every case—a latent artistic effect difficult to express. The reason for this difficulty is that the instinct to decorate—stronger in one person than in another—is never completely gratified because no decorative project, once it is begun, is ever permanently completed. The professional decorator must develop discriminating taste through studies of historic and contemporary

styles (see FURNITURE; FURNITURE, AMERICAN; FURNITURE, MODERN), and must be capable of creating original decorative schemes through comprehensive technical ability acquired only by long training and experience.

In its scope interior decoration includes—in its *residential* phase—the choice of designs for houses and apartments, as well as—in its *contract* phase—offices, clubs, hospitals, ships, theaters, restaurants, hotels, and other public buildings. The selection of appropriate color and pattern is as important in developing a decorative scheme as the textures and materials used. In its more comprehensive practice—of which only persons interested in it as a career need be concerned—

for practical needs. Information in the subject, however, is dependent upon the mutations of the times, because as old styles are discarded and new methods and techniques developed in their stead, there is a more flexible technique for decorating an interior that fits a corresponding more relaxed and flexible way of living: the occupant of a house or apartment is induced to express ideas in decoration not by rote, but for his own use and as a part of his own experience. The result is that an interior, instead of resembling a museum setting, acquires individual character and fresh interest.

Virtuosity is required in adapting interior decoration to the varying tempo of contemporary

A living room of the early Victorian period.

interior decoration is both a profession and a business, predicated upon merchandising and actual planning for living and working, with the business consisting mainly of selling interior furnishings, and the profession dealing with the skills of creating, or designing, complete interiors.

For the convenience of the reader, this article is divided into two sections:

1. Residential Interior Decoration
2. Contract Interior Decoration

1. RESIDENTIAL INTERIOR DECORATION

Opportunities in a fresh approach to decorating are enhanced by custom which, in the course of years, has changed the procedure from stylistic period decoration to the modern one of decorating

living. The professional decorator can, as in the past, make his own rules and depend upon his own taste for the achievement of desired results in decorating a room. The novice, however, is on safer ground in following the prescribed rules laid down through the years by trial and error.

Not least among the attractions of interior decoration is the diversity of its expression—the seemingly inexhaustible range of styling in furniture, fabrics, wallpapers, and floor coverings of every historical period—by which certain decorative effects are obtained.

Basic Principles.—The successfully decorated home—whether it is a house, an apartment, or a single room—is the most important material thing in one's life if it is to express the person-

Living room decorated in early American style by C. Eugene Stephenson shows lamp contrived from an old brandy jug and supplementary rheostat-controlled indirect lighting from behind antique carved figure over the fireplace.

ality of the occupants and be the perfect background for a social life bringing joy and contentment. It does not depend upon costly furnishings and great expense, but it does require assured knowledge of the basic principles of interior decoration and something of good taste.

The basic principles of design have existed for several centuries, and are likely to continue although they may appear variable because of changing fashions.

The interior decorator, contrary to general opinion, never deliberately attempts to create an "original" room. Instead, he applies his ability to solving the problems at hand, and the elements of the problem itself and his individuality of expression result in the ensuing originality. The talent required in aligning the various elements of a decorative problem into a flawless composition is what intrigues the decorator: the uncertainty of the outcome of an experimental color treatment, the way the room will appear at night in its lighting scheme, or the relationship of plain and patterned areas, proposed furniture arrangement, and necessary architectural changes when plans are still in the blueprint stage.

It is a simple enough matter to follow a given set of decorating rules in order to achieve a desired end, but a room assembled in such a manner marks the difference between mere "decorating" and true creative "designing," and the result is evidenced always by an effect that is just as certainly marked. It lacks individuality, for one thing, and there is consequently no personality. And nothing is drearier of aspect than rooms lacking in that "beautiful necessity," personality.

What, then, is the secret of conferring per-

sonality upon a room and giving it a vital, livable quality? The answer is simple: when an interior is not possessed of the spirit and enthusiasm of the decorator who created it, then that room lacks the vital quality and individuality recognizable at once as personality. And as every professional decorator knows, the surest method of acquiring personality—and charm—in a room is by means of style.

The Traditional Style.—Styles in interior decoration have always been influenced by those trends immediately preceding, and the decorator's main efforts therefore are devoted to interpreting them discriminately and to decorating interiors based on historical period connotation.

At the turn of the 20th century it was the custom to reproduce entire rooms in complete detail from some Italian villa or French château, but the decorator is now more concerned with the less identifying architectural aspects of a style in planning a room for present living. These are usually enhanced by furniture of traditional design, combined with contemporary items and fabrics woven in modern or traditional patterns.

The human body has always been the model to which furniture has been correctly scaled, and antique items that do not fall into this category are no more of good design than those made today which are not in good taste, nor will they be in correct proportion to the rooms in which they are placed.

Interior decoration in the traditional style, to be good, should be interpreted in a contemporary manner but with all the gracious and livable qualities of the old evident, being otherwise completely modern in convenient arrangements of

furniture and treatment of color scheme. Anyone with good taste and knowledge of the historical epochs in furnishings can re-create correctly an interior expressive of a defunct style. It may even possess grandeur, but unless its decoration expresses a 20th-century concept for living, it will be an anachronism. Moreover, sophisticated traditional interiors—for all their formal beauty of decoration—are not conducive to relaxed, comfortable modern living.

The Contemporary Style.—Modern decoration has resulted in an entirely new approach to decorative treatments with its precepts based on functionalism and a radically different conception of the decorative treatment of space. Certain social and psychological factors produced the conditions which developed it, and modern decoration

of doors and windows—conditions rarely found in present-day houses and apartments. This has resulted in the need for adapting the period styles—frequently with vexing results. If carried out correctly, as in the removal of moldings, etc., it entails a large expense for construction changes.

The owner of a house or apartment to be decorated in the modern manner has no such problems, inasmuch as the most obvious characteristic of contemporary styling is the result obtained by an avoidance of elaborate architectural details and moldings, and adherence to plain surfaces and straight lines. Conditions are generally accepted as found, and their proper development rests with creative ability and imagination and therefore offers interesting possibilities. Exposed beam ceilings, for example, are accepted as a part of the decorative scheme, as is asymmetry in plan and disposal of windows and doors, characteristics prevalent in contemporary architectural design.

Individuality in Decoration.—There is only one thing that will produce a successful room with individuality, and that is good taste backed by information in the subject of interior decoration. Individuality and adaptability to use have always been the most highly valued qualifications of a decorative scheme. A room that permits the expression of the owner's individuality will ever be a favorite. The average owner has a hobby, sometimes not well defined, in other cases most definite. To give expression to this hobby in the creating of background is the meaning of individuality in a most definite way.

The main factor inducing the various rooms in different houses and apartments to be unlike in the styling of their decoration can be attributed to either of two things: it may be money, or it may be taste. The interior decorator, in addition, resorts to individual design or period influences in any room which makes any pretense to distinction, and there is always this recognizable feature as the inevitable stamp. There should never be, however, any difference in the quality of the decoration between the budgeted room and a more elaborate one, the difference being in degree of elegance desired rather than in actual quality of decorative treatment.

With unlimited resources it is quite possible for anyone to create a beautiful room. But upon bringing the problem in decoration to the expert in home-furnishing, the client naturally expects competent guidance and the utmost value for the minimum sum to be expended. Good taste, besides being aesthetically satisfying, costs less in the long run than bad taste because it eliminates the elements of repeated alterations. The decorator may experience qualms of dismay and frustration over a budget at first, but in the end, because he possesses the knowledge of how to do it, he produces a satisfactory result which contributes comfort and beauty, at a saving, without sacrifice either of authenticity or good taste.

To create a successful interior also requires the ability to conceive of a complete interior picture, and not mere corners or groupings of furniture in the scheme. It involves a specialized study of traditional and modern styling with the information that makes it possible to assemble the details into a harmonious and pleasing unity. And with this ability to interpret detail it is essential to know the relative qualities of fabrics, upholstery work, curtains, furniture design, rug design and textures, wood and wall finishes, as

Small kitchen decorated by James H. Daggett, Jr., gains cheerfulness from colorful paper on ceiling and end wall. All furnishings are kept against walls, leaving free areas for kitchen activities.

became the popular style it is because the stage was set for it.

Whether one's choice is for the traditional or the contemporary style, the principles to be observed in decorating are the same for both. It is only in their application that they differ. Decoration in the contemporary, or modern, manner will evidence the same fine proportions and simple lines characterizing that of the traditional style with its period connotations. Modern furniture, as well as fabrics, floor coverings, and accessories will harmonize with their modern background. Interesting interiors can result by mixing traditional with contemporary design, and a modern room may well have a traditional item or two mixed in successfully, just as a traditional scheme gains by the addition of a modern background or an item or two with modern lines, and the use of modern fabrics and other materials.

Traditional decoration requires symmetry in wall treatments, flat ceilings and the axial spacing

INTERIOR DECORATION THROUGH THE AGES

Principles of good design outlive changing fashions in interior decoration. Designed around 1600, the room at left is from the teahouse of the Katsura Imperial Villa in Kyoto, Japan. The dining room below represents mid-20th century American design. Despite the differences in the periods and places in which they were built, both rooms embody similar ideas of restraint and proportion. Textures of wood and fiber contrast with oiled paper in the Japanese room, with marble in the American room.

THE AGE OF OAK

The treatment of wood became increasingly ornamental during the Renaissance, a trend exemplified by these French and English rooms. The room at right, from the château at Azay-le-Rideau (about 1520), Touraine, France, has a stone mantel and beamed ceiling. The wood paneling and pargeted ceiling of the Long Room in Haddon Hall, in Derbyshire, below, is in characteristic English Tudor style. The French Renaissance in full flower produced the ornate Louis XIII style seen in the grand salon, opposite.

NEOCLASSICAL INTERIORS OF THE 18TH CENTURY

Showing the influence of classical Greece and Rome, 18th century designers used restrained decoration and fine-scaled architectural detail. The interior at right is the salon of the château at Fontainebleau, France, in Louis XVI style, with Empire furniture. A neoclassical design inspired by Robert Adam is seen in the room below.

AMERICAN INTERIORS

Life Magazine

In the colonial period, kitchen, living room, and dining room were often combined, as in the 18th century interior above. Later American interiors drew heavily on English styles. The White House library, right, is in English Regency style, and the living room, below, in English Georgian style. The "Chinese taste" of the 18th century is expressed in the painted wallpaper in the Maryland parlor, below.

well as being familiar with an infinite number of new products applicable to interior use.

Out of the decorative materials available—the fabrics, floor coverings, wallpapers, furniture, and accessories—the interior decorator creates a new room or changes the aspect of an old one into an interior entirely of his own inspiration, expressive of his own time and temperament, worked out in the decorative mediums available as he visualizes them to be in the completed interior.
